The transformation of the social relationships of welfare is central to socialist and communist social policy and may be thought through in relation to six key aspects of social policy: (1) the priority afforded social policy, (2) the form of control over welfare provision, (3) the agency of welfare provision, (4) the nature of the relationship between welfare provider and user, (5) the rationing system adopted by the welfare institutions concerned, and (6) the assumption embodied in the policy regarding the sexual division of labour. This article reviews medical care and health policy in three countries, the Soviet Union, Hungary and Poland from the standpoint of a perspective of ideal socialist and communist medical care and health policy derived from an analysis of Marxist and allied critiques of capitalist medical care policy and theoretical work on socialist social policy. The author concludes that medical care policy in all three countries exhibits very few characteristics of socialist medical care. It also examines the possibility (for the moment suppressed) provided by the Solidarity movement in Poland of a new development toward a more genuine socialist medical care and health policy.

The article has been slightly abridged from the International Journal of Health Services Volume 14, number 3, 1984 and excludes the detailed review of medical policy in Hungary.

Socialist Medical Care Policy

The aim of this article is both to explicate a socialist conception of ideal medical care policy and to review medical care policies in the Soviet Union, Hungary and Poland to see whether they provide concrete examples of socialist medical care.

It is clear from George and Manning's (1) review of the few specific statements on socialism and health made by Marx, Engels, and Lenin that their emphasis is on those *causes* of ill-health located in the nature of capitalist society. As an example take Lenin's view that "thousands and tens of thousands of men and women, who toil all their lives to create wealth for others, perish from starvation and constant malnutrition, die prematurely from disease caused by horrible working conditions by wretched housing and overwork" (2). A socialist health policy would therefore be concerned primarily to prevent avoidable disease. There is far less in their writings on the particular form of curative health service that should be provided to cope with unpreventable disease.

Few subsequent Marxist theorists, addressing the nature of socialism have had anything specific to say about medical care. Bahro (3) is an exception here. His discussion of the need to alter the division of labour radically under socialism is illustrated by the example of the organisation of work in a hospital: "We can just as well imagine the everyday situation in a hospital, to take an example from a different sphere, one still more strongly burdened with the prejudices of the traditional division of labour, in which the entire staff consisted of people with full medical training, or other pertinent qualification, who also took part in all nursing and ancillary work and in social and economic functions as well." This twin concern with both preventive medicine—the fact that it will become a high priority under socialism—and the altered form of curative medical care will recur as the conception of socialist medical care emerges in this article.

Lesley Doyal's (4) excellent analysis of the causes of, and ways of curing, ill-health under capitalism is structured around these twin concerns. Her brief postscript to *The Political Economy of Health*, where she considers the implications of this analysis for the struggle for a healthier society, discusses both aspects. On the question of prevention of ill-health under socialism, she is sensibly cautious:

> Naturally we would not argue that a transformation of the mode of production would abolish illness—people will always become sick and die. But what we can show are the ways in which potentially avoidable illness has become prevalent under capitalism . . . [It follows that] the demand for health is in *itself* a revolutionary demand.

This concern with preventing avoidable ill-health is a touchstone of socialist policy. It would reach into every corner of working and domestic life. Not only would each work process be evaluated from the standpoint of whether it made workers ill or not, but also such diverse aspects of life as food, housing, transportation, and personal relationships would be affected far more than under capitalism by considerations of their health-enhancing potential. Changes in life-style in relation to all of these things would be a matter of general public concern and action. Necessary economic and social changes that would enable people to live, eat, and relate differently would be a matter of medical policy.

On the form of curative medical care under socialism, Doyal (4) writes:

> The struggle must therefore go beyond the immediate demand for more state-organised medicine, towards a critical re-evaluation of the more qualitative aspects of the current organisationof medicine and a redefinition of our health needs. This is not, of course, to suggest that in a socialist society all existing medical knowledge and skills would simply be abandoned in favour of something called "proletarian medicine" . . . [But] no technology would be used uncritically and without some assessment of its value according to criteria which had been democratically decided upon . . . Hence a socialist-health service would not only have to provide equal access to medical care but would also have to address itself seriously to such problems as how to demystify medical knowledge and how to break down barriers of authority and status both among health workers themselves and also between workers and consumers.

The theme of the necessity of changing *the social relationships embodied in medical practice* under socialism is taken up by other Marxist critics of the National Health Service (NHS) in Britain. After criticising existing left orthodoxy, which sees within the existing structures of the NHS a more-or-less socialist form of medical care requiring only an injection of formal democracy, Mick Carpenter (5) argues:

> A socialist health service . . . will be one where all barriers of hierarchy and mystification, between health workers and between them and the sick people they work with are torn down. It will be a health care provided neither because of the material necessity

of wage workers nor out of an imposed set of obligations which fall upon certain people, mainly daughters and wives.

Vicente Navarro (6) has pursued this theme of changing the social relations of medical practice, insisting that "Communist medicine is not bourgeois medicine better distributed but, rather, a qualitatively new form of medicine created by new relations of collaboration and cooperation in the process of the production and reproduction of health."

The forms of medical technology and science themselves are therefore likely to be transformed under communism. This is not to argue that all capitalist medical science and technology is false or wrong, merely that capitalist social relations of production are reflected in the present choice of research areas and in the forms of technology used. Different social relations, those of reciprocal cooperation, would be reflected in the technology of communist medicine. An attempt to specify the way medical technologies under capitalism reflect the social relations of capitalism has been made by the Radical Science Journal collective (7). For instance, Shelly Day (8) suggests that obstetric technology reflects both capitalist and male interests in the way it reinforces the passive role of women just at the point where (ideally) their active control of birth process is required. Postnatal depression, Day argues, may result from this highly contradictory experience.

Recently a number of authors and organisations have attempted to construct in a more concrete way the expectations we should have of a genuinely socialist medical care policy. Colin Thunhurst (9) has argued that the scope of health services should be increased to embrace an occupational health service controlled by workers. Alex Scott-Samuel (10) has suggested the need for a socialist epidemiology in which a community diagnosis focus would be central, where questions would be asked by those who live in a locality about who is ill and why and what could be done to create more healthy living and working conditions. It has also been argued (11) that the service should allow for alternative modes of treatment, and for the involvement of people in the provision of services in the way that is now prefigured by some Well Women clinics. There should be a "different relationship between health team and patient . . . [providing] the patient with the opportunity to participate in a fully informed decision concerning the course of treatment."

The Politics of Health Group (11) has argued that we need to challenge the medical dominance and "hierarchy" in the health service; to give patients more say in their own health care; to capture more control over our health; to give "community care" real meaning; to achieve more and better routine health care for non-life threatening complaints; and to fight the *causes* of ill-health.

One organisation that has tried in its practice to prefigure these conceptions of a genuinely socialist medical care policy in the here and now is the Community Health Council in Brent, North London. Its publication *It's My Life Doctor* (12) designed for use by the local community, sets out seven common medical problems, how they might be prevented, how the National Health Service fails in relation to them, and what kind of preventive and curative health policy would be more appropriate to the needs of people suffering such problems.

The feminist critique of medical care practice under the NHS is also well advanced (13). A socialist health service that responded to the feminist critique would abolish the sexist content of medical practice. Thus, women's ailments and conditions (e g, menstruation, menopause, pelvic inflammatory disease) would be given proper attention. Gender stereotyping of women through the use of such labels as "hysterical" would be challenged. Women would take control over their bodies in matters of sexuality (abortion on demand) and childbirth (natural childbirth). The form of service would be altered so that women did not just perform the caring functions such as nursing while men performed a separate curing function. Nor would women be left to carry the burden of caring for the family. A socialist epidemiology would also incorporate a feminist epidemiology. Central to this would be the recognition that the disabling double burden of paid work and domestic work should be alleviated.

The conclusion so far that socialist medical care would embody a transformation in the social relations of medical practice reflects the general conclusions I have drawn elsewhere (14) that the transformation of the social relationships of welfare is central to socialist and communist social policy. I have argued that the conception of a transformation of social welfare relationships needed to be thought in relation to six key aspects of social policy: 1) the priority afforded social policy, 2) the form of control over welfare provision, 3) the agency of welfare provision, 4) the nature of the relationship between welfare provider and user, 5) the rationing systems adopted by the welfare institutions concerned, and 6) the assumptions embodied in the policy regarding the sexual division of labour. I also argued that a distinction should be drawn between socialist and communist social policy. The summary of our expectations of both socialist and communist medical care policy indicated in Table 1 is based on those general considerations relating to social policy as a whole and the specific considerations reviewed so far in this article relating to medical care in particular.

A few comments on Table 1 are necessary. First, it has been argued so far that a policy for health under socialism (and communism) would not just be a policy of providing a transformed medical care service. Issues of medical care would be redefined into issues of health, which in turn would become issues of working conditions, housing, and economic and social life in general. It has been argued (15) that a socialist conception of health can only be developed once medical care itself is removed from the centerpiece of analysis. The view taken here is that in assessing progress in any socialist society, we need to consider both the form that socialist medical care provision will take (to cure and care for those suffering from unavoidable disease) and the extent to which a socialist health strategy has been developed that places equal emphasis on changing social conditions to prevent avoidable ill-health. The table attempts to show both how the form of medical care would be different and how a socialist health strategy would be developed (though perhaps concentrating more on medical care policy than on health strategy). Measures of whether a socialist health strategy is being developed are provided by the criteria dealing with the priorities of medical care as between cure and prevention, and by the assessment of the outcome of medical care (health) policy in terms of morbidity and mortality.

Second, the priority given to medical care under socialism cannot simply be measured in terms of the resources put into the health sector of the economy, whether in terms of money, person power, or facilities. While we would expect health ex-

penditure to become a higher priority in the initial stages of socialist development, the infusion of resources is clearly no measure of socialist progress in medical care in societies already at the threshold of communism. As we have argued, greater benefit in terms of the health of the population is more likely to come from transformed working and living conditions that prevent avoidable ill-health. A measure of the output of the health service in terms of morbidity and mortality rate is a better indication of the priority afforded to a society's health than a measure of money spent on the health sector. A lower level of morbidity and mortality is also likely to reflect the importance attributed by a society to the preventive aspects of medicine, which are otherwise so difficult to quantify.

What people suffer and die from is another important measure of socialist progress. This applies both to underdeveloped and developed socialist societies. In the former, the eradication of the preventable infections and communicable diseases will be a crucial indicator; in the latter, a reduction in the incidence of the new illnesses of developed societies will be a measure. Socialist and feminist epidemiology has already made progress in identifying the social causation rooted in the capitalist mode of production of such conditons as cancer and cardiovascular diseases. A genuinely socialist health strategy would therefore be expected to have acted upon the conclusions of this new epidemiology and effected changes in the relevant social conditions which will show up in terms of reduced morbidity and mortality from these new "capitalist" diseases.

Third is the rationing of medical care. Elsewhere (14) we have concluded that services did not necessarily have to be free at the point of use to be allocated along socialist lines. As long as incomes were more-or-less equalised, and as long as the commercialism of the private market was no longer present, the attaching of a price to a service provided by the state (e g, housing) could permit the users of a service to ration their own use of the service (a smaller or bigger house?) according to their own set of priorities. Now there is the argument that charges for health services, even if incomes were equalised, should not be made because an individual use of the service has indirect impact on the health and welfare of others, and everyone's use must therefore be encouraged even if an individual would order her or his own priorities differently. Indeed, there is even the argument for

Table 1

Expectations of socialist and communist medical care policy

Aspect of social policy	Aspect of medical care policy	Socialism	Communism
Priority	1. Outcomes in terms of health	Less and more equal morbidity and infant mortality than capitalism; greater and more equal life expectancy	Less and equal morbidity and infant mortality; greater and equal life expectancy
	2. Resources in terms of money	Higher expenditure than capitalism	Need for higher expenditure may no longer exist
	3. Resources in terms of person-power/facilities	Higher level of resources than capitalism	Need for higher level of resources may no longer exist
	4. Priorities in terms of cure, care, prevention	Prevention and care prioritised	Prevention and care central
Control over welfare provision	5. Central control	Central direction with political cadre influences	Centre provides democratically resolved planning guidelines only
	6. Local control	Democratic worker and user involvement.	Mass participation in policy resolution and implementation
	7. Control of medical technology industry	Nationalised and progress toward socialised relationships	Socialised working relationships within industry and between it and the health service
Agency	8. Agency of provision	State, workplace, family and market giving way to community provision	Community provision
Relationships between provider and users	9. Status of doctors	Lower than under capitalism	Equal status with all workers
	10. Division of labour in medicine	Reduction of vertical and horizontal divisions	Abolition of vertical divisions; movement between horizontal divisions
	11. Nature of medical technology	Progress toward new forms	New forms of medical technology reflecting communist social relations
	12. Status of patients	Higher, accompanying deprofessionalisation of doctors	Equal status with providers
Rationing systems	13. Region and class access, usage, and outcome	Progress toward equality	Equal access, usage and outcome
	14. Rationing procedures between individual patients	Free usage with access rationed by work and need according to democratically determined formulae	Free usage with access according to self-perceived need
Sexual divisions	15. Sexual division in medical care employment	Progress toward no division	No sexual division of medical labour
	16. Sexist content of medical practice	Progress toward no sexist content	No sexist content of medical practice

a practice of financial inducements to use a particular service for the beneficial impact that an individual's use of it might have on the health of others. This assumption of nil direct cost to the individual consumer of the service is built into the table as a measure of socialist progress (even though this may not be such a crucial aspect of a socialist health service as is usually assumed). It can be taken as one measure of a nation's collective commitment to the health of all its members.

There are a number of other problems associated with the criteria used to determine socialist and communist progress in medical care, including those of putting into operation the general measures indicated in the table. How exactly is the "lower" status of the medical profession to be determined? How is progress toward deprofessionalisation to be measured? What are the indicators of the abolition of the sexist content in medical practice? These problems of operationalisation are often compounded in practice by the non-availability of data. Despite these difficulties, however, I believe it is possible to draw some general conclusions about the socialist status of the medical care policies of the countries studied.

Soviet Medical Care Policy

There are many accounts of the Soviet health service by writers of various shades of socialist opinion. These vary from the openly enthusiastic (16) to the fundamentally critical (17). The summary survey provided here is distilled from these and a number of other secondary sources (18-20). For the discussion of the extent to which there are sexist aspects to the organisation and content of medical care, more general works on the position of women in Russia have been consulted (21-23). Detailed references are not generally provided to these frequently used sources.

George and Manning (1) state that, at the outset, Bolshevik medical care policy goals included: comprehensive qualified medical care; availability to everyone in the population; a single, unified service provided by the state; a free service; extensive preventive care, with the aim of creating a healthy population; and full worker's participation in the health service. While many of these goals continued to guide policy and many were achieved, the development of medical care policy also came to be shaped by other historical exigencies, especially in the periods of socialist retrenchment during the New Economic Policy (1921-1929) and of intense industrialisation and forced collectivisation of the 1930s. The way these factors influenced medical care policy and the final outcomes of policy will now be considered in detail, under the following headings: the priorities of medical care; the control of medical care; the agency of provision of services; the relationships embodied in medical care; the agency of provision of services; the relationships embodied in medical care; the rationing procedures adopted; and lastly, the extent of sexist organisation and content of medicine.

Priorities of Medical Care

Does Soviet medical care live up to the expectation we would have of it if it were socialist in terms of 1) providing more health care resources than comparable capitalist societies, 2) distributing health care resources and activities disproportionately in favour of prevention, and 3) providing for a healthier population than populations in equivalent capitalist societies?

The Soviet Union spends a far smaller proportion of its gross domestic product on health care than the Common Market countries. Michael Kaser (18) estimated that 2.8 per cent of GDP was spent on health care in the USSR in 1968, compared with 5.1 per cent of GNP for the United Kingdom, 8.0 per cent for Italy, and 5.0 per cent for Ireland. A more recent estimate (24) based on 1974 figures suggests this has dropped to 2.5 per cent. However, in terms of the number of doctors and hospital beds per head of population, the Soviet Union is far ahead of these same countries. There were, in 1977, 34.6 physicians per 10,000 people in Russia compared with 2? ? in the EEC as a whole. There were 121 hospital beds for the same population in 1977 compared with 95 for the EEC (24). These details are summarised in Table 2. The apparent paradox between low expenditure levels and high-level provision is resolved once it is understood that first, there has been far less capital expenditure on Soviet medical care compared with the EEC. In 1970, 5 per cent of health service outlays was devoted to capital expenditure in the USSR compared with 10 per cent in Britian in 1971-1972 (18). This explains the often reported poor quality and overcrowding of medical care institutions and the lack of surgical and pharmaceutical equipment that occurs from time to time.

As to the priorities within health service expenditures, it is clear that, despite the early creation of a preventive arm of the health service, the hospital sector of medicine dominates all the other sectors and consumes the largest proportion of resources. The Bolshevik government in the very early days established the important departments of sanitation and epidemiology, with responsibility for flying propaganda squadrons combating social sources of disease. This was seen in 1928 by one sympathetic commentator (25) as "offering a good example of the new attitude and principles of Soviet medicine." Even in 1925, however, expenditure on sanitary and hygienic education and on campaigns against contagious disease consumed only 2.6 per cent of the health service budget (25). The Council on Medical Education in 1925 aimed to produce doctors with not only a thorough scientific understanding of the connection between biological

Table 2

Medical Care Expenditures, Resources, and Outcomes in the Soviet Union, Eastern Europe, and Comparable Capitalist Countries[a]

Indicator	Soviet Union	Hungary	Poland	Nonsocialist comparison
Percentage of GDP spent on medical care	2.5[b]	3.3[b]	3.9[b]	5.1-6.7[c] (EEC states)[d]
Population/physician	289[e]	435[e]	606[e]	455[e] (West Europe)
Population/hospital bed	82[e]	114[e]	113[e]	105[e] (West Europe)
Infant mortality/ 1000 live births	27.8[f]	24.3	22.4[f]	11.4-17.6[e,f] (EEC excl. Portugal)
Life expectancy:				
Male	66.5[f]	66.1[f]	66.5[f]	70.2[e]
Female	74.3[f]	72.8[f]	74.9[f]	76.3[e] (Britain)

processes and disease, but also with: 1) sufficient social science background to enable them to understand current social life and world events: 2) the materialist point of view, which is essential to a correct understanding of the mutual relationship between an organism and its milieu, 3) the social service point of view, which takes into account the working conditions and home life of the patient; and 4) the knowledge and ability not only to treat diseases, but to prevent them. However, an analysis of the curriculum of the Medical School of Moscow University of 1925-1926 suggests that even if we are to include such topics as "Historical Materialism and the History of Revolutionary Movement," only about 5 per cent of the content was directly related to these four points. The socialist idea of creating a new medical knowledge and practice derived from new social relations of production reflected in a new division of labour between doctor and patient, does not seem to be borne out by the existence of this disease- and clinically-oriented curriculum.

Turning to the present day, the proportion of doctors working in hospital care compared with ambulatory care is increasing. There is more rapid increase in the number of doctors specialising in tertiary medicine (e g, surgeons, neurologists, psychiatrists) (17). One estimate (19) of the proportion of health care resources devoted to "environmental health and physical education" is 4.8 per cent. There is evidence, though, that the quality of primary care is better than that of hospital care.

The outcomes of the Soviet health service, measured in terms of morbidity and mortality rates, cast considerable doubt on whether sustained socialist progress in health has been achieved. During the early years of the Revolution, progress was made in decreasing mortality and morbidity. By 1925, even though industrial output and grain harvest were below 1913 levels, infant mortality had fallen to half of the pre-Revolutionary level (20). This progress, when compared with that of the West, has now been lost, as can be seen from Table 2. Today, mortality rates for infants and adults compare very unfavourably. There were 27.8 infant deaths per 1000 live births in the whole of the USSR in 1975 and 19.2 per 1000 in the Ukraine Republic, compared wth 15.7 in Britian in 1978. Infant mortality actually rose from 1971. when it was 22.9 per 1000, to 27.9 per 1000 in 1974 (20). Life expectancy was 66.5 years for males and 74.3 years for females for 1970-1975, compared with 70.2 and 76.3 for Britain in 1977. There is evidence that life expectancy for adult males began to decline in the mid 1960s. Age-adjusted death rates for adults rose from 861 per 100,000 in 1965-1966 to 955 per 100,000 in 1972-1973. The largest increase in mortality has been in the 40-59-year category (20). The absence of morbidity and mortality data analysed by social class does not permit any assessment as to whether there has been greater equalisation in longevity and mortality.

An analysis of the diseases Russians now suffer and die from also provides a disturbing commentary: "As the death rates from infectious disease have fallen in the Soviet Union, mortality from cardiovascular diseases and cancer has risen, both relatively and absolutely. The force of these modern epidemics has been sufficient to *raise* [the] age adjusted death rate by 18 per cent over the last decade" (20). Cooper and Schatzkin (20) comment that "social environment ... typical of capitalist society ... can be shown to be responsible for these mass diseases." The first Commissar of Health in the USSR said: "There is no interest in concealing the social character of these diseases... the social causes of diseases among working people are found out in order to remove them." But Cooper and Schatzkin (20) conclude: "The opposite [now] appears to be the case: disease is promoted, its social character is obscured and avoidable hazards are not removed."

Control of Medical Care

The early days of the socialist experience in Russia (1917-1921) provide perhaps some of the most potent examples of the possibilities of socialist medical care policy in terms of formal control over medical care policy and institutions. The direct confrontation in the 1920s between the medical profession's Pirogov Society and the Bolsheviks, which was won by the Bolsheviks with the aid of the health workers' union, should be noted. This struggle curtailed the special privileges of the profession and the control it had over medical care institutions at that time. This early period of Russian history provides us with the best practical examples of how the important issue of control of health service and other welfare institutions will be raised under socialism. The debate, which is also recalled by Navarro (17), between those who favoured control by the workers in health service institutions and those who favoured control by soviets or delegates of workers in a locality, is one which poses for us now the question of what form democratic control should take in any future socialist society. In this example, the form of administration chosen was one in which doctors, as state-salaried employees, had no special professional access to power, with the day-to-day management of health service institutions invested in a nominee of the local soviet, who would be advised by an elected committee of health service workers. Those who favoured control of each institution by a democratically elected committee of workers of that institution were criticised for not understanding the needs of overall planning and were defeated.

With the eventual erosion of any active life in the local soviets and as soviets became empty conduits for the rule of an increasingly centrally controlled and Stalinist Communist Party that determined even local policies through the national budget, any vestiges of active worker participation in—let alone control of—health service institutions disappeared. At the same time, the initial decline in the power of the medical profession was reversed. The Ministry of Health has relied heavily in more recent years on the advice of the increasingly institutionalised medical profession, and it has become the practice for all directors of health service institutions to be qualified doctors. The ratio of income between doctors and nurses is now as large as 10:1 (17). Indeed, George and Manning (1) conclude that, nowdays, "Soviet health care [is] centrally controlled to meet the requirements of industrialisation and the academic interests of medical scientists." However, despite this heavy reliance today on medical personnel to run the health service centrally and locally, a large proportion of these administrators are Communist Party cadres and are, of course, in the last analysis, responsible to the Central Committee of the Party (17). The socialist notion of political control of policy through the active involvement of party cadres at all levels of administration is theoretically maintained; however, from the point of view of an ideal socialist medical care policy, the ideas and

practice of these cadres leave much to be desired. They no longer appear to favour—if they ever did—the genuine mass involvement in health matters which should be the hallmark of communist medicine.

Agency of Provision of Services

The main agency of provision of health care in Russia is the state. Hospitals polyclinics, feldsher outposts, and so forth are all run on behalf of the state by local councils, but there is scant evidence of mass participation in, or democratic election to, the local bodies which run these institutions. The workplace features quite significantly in the system of provision. Under the Stalinist industrialisation policy, a large number of health centres were established in industrial enterprises. There ranged from 100-bed hospitals to the provision of a nurse. They were organisationally separate from the Soviet-run health services and were part of a policy of giving priority to preventing loss of industrial production. The demands of industrialisation and the needs of workers coincide to some extent here, but it is not easy to determine how far these services give priority to the latter over the former when it comes to a direct conflict between them. The scarcity of Russian data on disease and death analysed by social group, and the nonpublication of accident data, is perhaps indicative of which priority is uppermost. There is further evidence of the priority given to workers in Russia by the development of separate health service institutions run by and for railway workers and the wide provision of rest cure and convalescent homes and holiday villas by trade unions for their members.

The private market is an important provider of medical care services in the Soviet Union, although there is some legal and some illegal private practice. Abortion constitutes on example. Additionally there are autonomously financed medical institutions, or "paying polyclinics" (*platnaya poliklinika*), in Moscow and other big cities where patients pay a small sum for prearranged appointments with specialists. Like the nonpaying polyclinics, these are run by the local authority and are not really examples of the operation of a competitive market in medicine. They provide, however, a commentary on medical care rationing procedures used. If you can pay, you get better treatment. Although it is discouraged, payment for treatment is also made on a regular basis to doctors and nurses in ordinary state hospitals. In the 1960s the table of customary payments ranged from 5-25 roubles for attention in hospital to 500 roubles for a course of treatment for venereal disease by a senior specialist (18). Women in the family still provide a large amount of medical care in terms of nursing the sick and elderly. This is institutionalised in the provision made for women (not men) to receive state grants for time off work to look after sick children.

Relationships Involved in Medical Care

Turning now to the various aspects of the relationships involved in medical care, we must remember that the status of the medical profession in the Soviet Union is lower than in the West. The division of medical labour is similar, however. The only exception is the feldsher system of partly trained nurses-midwives-practitioners who practise in rural areas. This is a socialist innovation, but one inherited from pre-Revolutionary days. Indeed, early Bolshevik policy, later abandoned, was to get rid of these "second-class doctors."

Whether or not Bolshevik policy initially understood that socialist medicine must redefine the practice of medicine, in such a way that a change in the division of labour takes place in both the vertical and horizontal senses, there is no evidence that this policy was pursued in later years. Indeed, the absence of a family doctor system brings specialisation and mechanistic medicine even into the diagnostic stage of the polyclinics. George and Manning (1) write:

> For example, the Ministry of Health recently stated that "it is impossible to conceive t[illegible]ly a single doctor with a broad background co[illegible]arantee highly qualified care for patients suffering from a variety of illnesses which are frequently complicated to diagnose and treat." Such a view in contrast to the major incidence of relatively simple and self-limiting illnesses brought to primary-level physicans, clearly indicates the interest and perception of medicine oriented towards academic specialisation rather than patient needs.

There is also the practice of tipping doctors, which reflects the esteem in which doctors are held by patients. There are no adequate independent complaint procedures against doctors. There is no free choice of doctors by the patient. These points contribute to the conclusion that there has been no sustained challenge to the relationships involved in the capitalist practice of medicine in the Soviet Union. Navarro (17) is convinced that the Soviet system of health care is dominated, as in the West, by what he terms technologicalisation, depoliticisation, hospitalisation, and urbanisation.

Rationing Procedures

Does Russian medical care embody socialist aspirations in its system of distribution and rationing? There is evidence (1) of a sustained attempt to provide for a reasonable degree of territorial justice between different regions of the USSR in terms of doctors and hospitals, although the quality of service probably varies geographically more than the quantity. The emphasis on central planning has enabled this achievement to be registered. Within each region of the country, however, resources are concentrated in the urban areas.For example, Moscow in 1972 had 76 physicians per 10,000 inhabitants compared with 28.3 for the country as a whole (17). There does not appear to be a larger number of feldshers to compensate for this in the underprovided-for rural areas.

It is more difficult to be precise about the allocation of services between social classes and groups. The urban concentration of resources, taken together with the development of workplace-based health services, reflects a concentration of provision in favour of the urban working class as opposed to the peasantry. There is, however, no hard evidence about health service usage by social class, or even, as we saw earlier, health outcomes by social class. Nor is the impact of any differential usage on health known.

The fact that polyclinics are, for example, open on Sundays for all services is a reflection of an overt policy to make services available in a way that fits the needs of working people. Against this, however, has to be set the existence of closed-access clinics and hospitals such as the colloquially termed *Kremlouka* for senior state and party officials. There is also a special polyclinic for scientists with a doctorate. Furthermore, the people who have privileged access to these facilities are the ones who are likely to be able to purchase pharmaceutical preparations, not otherwise readily available, in closed-access shops (*Zakrytie raspredliteli*) (18).

The medical care services are for the most part free, with the exception of the paying polyclinics described earlier. Price is generally as a rationing device only in relation to drugs, dentures, spectacles, and surgical appliances, and there are the exemptions for the young and the disabled. About 30 per cent of the cost of drugs in 1970 was recoverable by charges, which compared with 50 per cent in Britian (18). How services that are free are actually rationed informally between competing consumers is again not known. Waiting lists and queues clearly operate, but there is no discussion of the impact of these informal *ad hoc* rationing devices on usage by class, age, or sex in the literature reviewed.

Sexual Divisions

There are two aspects to the impact of the Russian health service on women: first, the extent of and nature of female involvement in health service employment; and second, the degree to which the practice of medicine is sexist in its content. There is no doubt that women have been recruited to all ranks of the medical and nursing professions and to ancillary employment in the health services in far larger proportions than in equivalent Western health services. Ninety per cent of primary care physicians, 70 per cent of nonprofessional workers, and 50 per cent of managers and administrators are women. Eight-five per cent of the total health labour force is female (17). (It must be remembered that the status of even senior professional health service employees is lower in Russia than in the West.) Women moreover occupy a small proportion of the more senior posts. Only 20 per cent of medical professors are women. There is also some evidence that, as the status of doctors increases, the employment of women in this sphere is declining. Only 54 per cent of those now embarking on medical training are women, and men are admitted into medical studies with lower grades than women (21).

Evidence to allow any firm conclusions to be drawn about health care as it affects female consumers is far more patchy. The right to abortion has sometimes existed in Russia and at other times, especially from 1936 until the 1960s, has been expressly removed (26-28). The demographic needs of the country have, in later years, played the most important part in influencing this policy. Childbirth nearly always takes place in hospitals. In so far as medical care and allied child-care facilities have been developed with the extra express "needs" of women in mind (e g, their right to paid time off to nurse a sick child in hospital), it has been argued that they have been predicated on the twin requirements of women as workers and as mothers. The emphasis on the role of women in Russia as mothers, despite their role as workers, is well-known and, some would argue (29), was even present in the work of Alexandra Kollontai in the 1920s. Indeed, it would appear that there is resistance among some Russian women to the demands of this double burden, so that genetic and psychological counselling is now a service being provided in Moscow to encourage childbirth and happy marriage (21). Lapidus (23) concludes:

> Soviet sociological analyses show no sensitivity to the distinction between reproduction—a biological fact—and child rearing or housekeeping—socially learned roles whose relationship to biology is not given but requires explanation. The equation of femininity, maternity and domesticity is virtually universal, and the recognition that roles might be socially assigned rather than endowed by nature is largely absent.

Although Lapidus does point later to emerging Russian examples of critical literature that attempt to challenge this idea (literature that goes so far as to present the case for reduced working hours for men to overcome the sexual division of labour), it is more than likely that medical care texts, education, and practice in this area are predicated on conservative and antifeminist assumptions. A feminist analysis of Russian medical textbooks and medical practice is awaited.

It is possible now to go some way toward determining whether any or all of the 16 expectations of socialist or com-

Table 3

Extent to which Socialist and Communist Medical Care Expectations have been Realised in Existing Socialist Societies

Aspect of medical care policy[a]	Soviet Union	Russia, 1917-21	Hungary	Poland	(Solidarity's proposals)
1. Outcomes in terms of health	No[b]	No	No	No	(Soc)
2. Resources in terms of money	No	No	No	No	(Soc)

16. Sexist content of medical practice	N.A.	N.A.	N.A.	N.A.	(N.A.)
Number of socialist expectations realised	6	8	5½	4½	(12)
Number of communist expectations realised	0	0	0	0	(5)

Notes: a See Table 1 for an explanation of criteria used in this table.

b Abbreviations: N.A., inadequate information available to enable judgement to the made; No, the socialist or communist expectation has not been realised; Soc, the socialist expectation has been realised; Soc/Com, the aspect of the service could be attributed to the realisation of either socialist or communist expectaion; ½ Soc, in some respects but not all, socialist expectation has been realised.

munist medical care delineated in Table 1 have been realised in the Soviet Union. The results are tabulated, along with those for the other countries to be reviewed in this article in Table 2. For only five of these indicators is it felt appropriate to claim unqualified socialist achievement in contemporary Russia, with some indication of this in a further two. The five relate to the level of service provided (more doctors and beds), the nature of the central control of the health services (political), the agency of provision of medical care (state and workplace), the status of physicians (lower), and the position of women as employees of the service (large percentage). Even some of these have to be qualified, however, and, importantly, there is evidence of recent reversal. The status of doctors appears to be rising, the position of women in the profession declining, and the influence of medical expertise on central policy increasing.

It is, of course, possible to interpret even these five indicators of socialist medical care policy in a different light. It could be argued that these aspects of the service are compatible with, and necessary to, the needs of an exploitative state capitalist or state bureaucratic ruling class. Their apparently socialist character may conceal other reasons for their existence. A society in which the accumulation needs of the ruling group took precedence over the consumption needs of the working class would quite likely adopt tight central control over health planning, develop a workplace-based system of health care to ensure productivity, limit the independent influence of doctors (and be more successful at this than a capitalist ruling class operating in conditions of parliamentary democracy), and pull all women into the labour force. Indeed, such a state capitalist or state bureaucratic class, while adopting these measures, would equally not adopt many of those measures which we have associated with socialist medical care but which Russia does not exhibit. Such a class would not spend much on health, would not allow a democratic form of control over its institutions, would not encourage preventive measures which clashed with accumulation needs, and so on.

There is certainly no evidence of communist achievement in Russian medicine. Paradoxically, however, in the early days of Revolution there was some such evidence in, for example, the democratisation of the service at a local level. This development has long since been reversed. There was also an important stress earlier, at least in official pronouncements, on preventive medicine. Russian medical care, then provides us with very few concrete examples of our conception of ideal socialist medical care, and none of communist medical care.

One final cautionary note. It was stated earlier that in one particular way the table of expectations of socialist and communist medical care (Table 1) underemphasised the fundamental break with capitalist medicine that communist medicine entails. Communist medicine would involve itself with all aspects of social and productive life (working conditions, living conditions, eating habits, relationships) in so far as they affect health. This review of Soviet medical care has only noted such wider aspects in small ways, and then negatively, e g, in relation to the pattern of disease, which is similar to a capitalist one. It is most unlikely that all aspects of social life in the Soviet Union are evaluated in terms of their impact on health. The conclusions drawn therefore probably overemphasise the socialist nature of Soviet medical care policy.

Hungarian Medical Care Policy

I do not intend to provide as exhaustive a review of medical care services in Hungary or Poland. Both countries occupy similar positions as members of Comecon and are, as we shall see, modelled in many ways on the Soviet experience, with the important difference that they had this experience imposed on them after the Second World War.

There is a limited secondary literature available on the Hungarian health service. The main sources used here are Kaser (18), Ferge (30), and World Health Organisation (WHO) publications (31), which are supplemented by personal observation and by discussions with the small group of social analysts working within the Institute of Sociology in Budapest.

Health care is universally available in Hungary and largely free at the point of consumption; however, this university was finally achieved only in 1975. The insurance basis of the scheme excluded about 15 per cent of country dwellers, in 1960, but this was reduced to about 1 per cent by 1972 as a result of the collectivisation of agriculture that took place between 1958 and 1962. Those excluded were helped on a means-tested basis with medical fees by the social aid committees of local councils. Before the Communist Party came to power after the war, a large proportion of the population was excluded from coverage—except for the 133 days of Hungarian Soviet Republic of Bela Kun in 1919, a genuinely Hungarian-born revolutionary workers' council type of government, under which medical care was in principle provided free to all. (This regime was crushed and replaced by an authoritarian right-wing regime.) The system of health care in Hungary is remarkably similar to that in Soviet Union in a large number of aspects, although there is less factory medicine, more private medicine, and no use of feldshers.

The overall conclusions about Hungarian medical care are summarised in Table 3. They are remarkably similar to those for the Soviet Union, except that whereas the socialist nature of aspects of Soviet health care was in some doubt because of non-availability of data, the availability of such data for Hungary defines these aspects more clearly as nonsocialist. This is particularly the cause in the matter of inequality of morbidity and mortality by social class. Hungary differs from the Soviet Union only in not ever having experienced the brief democratisation of the health services that Russia did in the early years of the Revolution.

Polish Medical Care Policy

The purpose of including Poland in the survey is to examine whether the working-class uprising led by Solidarity in 1980 and 1981 might have made medical care policy more genuinely socialist had it not been suppressed. In the discussion of Soviet and Hungarian medical care polices, little mention was made of the existence of any social forces struggling against the current form of provision. This was mainly because there are none at present having much impact. Poland, by contrast, provides us with a modern laboratory in which to test out the theory that working-class struggle against the existing form of socialism contains within it the seeds of a struggle for a more genuine type of democratic socialism. Clearly Solidarity drew into its wake all manner of ideas, themes, and groupings whose aims may not have been the better development of socialism; however, these counter-revolutionary tendencies were insignificant (32).

More interesting is whether the end result of the struggle for socialism by Solidarity might have led to a pluralistic conception of socialism in which self-managed enterprises became increasingly subject to market forces to the possible detriment of the overall socialist objective. For our purposes here, we focus on the demands and the forms of struggle that arose in the course of the life of Solidarity as far as medical care is concerned.

In almost all respects, Polish medical care policy is like that of the Soviet Union and Hungary. Data on health expenditure and medical care outcomes are included in Table 2. The number of doctors and hospital beds per head of population is small compared with both the other Eastern European countries studied and Western Europe. A full account of medical care policy in Poland can be found in Millard (33, 34) and Kaser (18). Millard (34) summarises his findings as follows:

> The health service has remained in a state of crisis, currently worsening as a result of mounting economic dislocation and political tension. Inadequate access to treatment, lack of continuity of care, poor quality of care, profound shortages of drugs and supplies, and the absence of preventive medicine are some of the manifestations of this crisis. Its main causes lie in the political weakness of the Ministry of Health, with consequent underfunding and the non-fulfilment of its plans. This situation is exacerbated by continuing organisational fragmentation, the neglect of primary care, existence of conflicting aims in health policy, and the dominance of an ideology of clinical specialism.

Rather than reviewing the Polish health service systematically in terms of the six questions and 16 criteria applied to the Soviet Union and Hungary, I shall concentrate on three aspects of policy which, taken together, indicate just how far the Polish health service had reached a state of crisis even worse than in other Eastern European countries surveyed. As we shall see later, it was precisely to these aspects of medical care policy that Solidarity paid most attention in its proposals for fundamental change in Polish society. The three aspects are the failure of the central planning system, the inequalities of access and corruption involved in access to decent health services, and the neglect of preventive medicine. The summary Table 3 does, however, evaluate the Polish medical care service in terms of all the criteria established earlier.

Crisis of Planning

Central planning of medical care and the implementation of the plan at the local level are in the hands of people placed in position through the system of *nomenklatura*. This party control of key positions extends as far as directors of important medical establishments (32). It was described in the critical report prepared by members of the Experience and Future Discussion Group (DiP) (35) in Warsaw in 1980 as "the personal merry-go-round," which enables a person listed to be appointed to a post conferring equivalent or even higher status after having bungled a previous job. The tendency in this situation is for particular aspects of plan fulfilment to be nominally achieved even by cheating or misrepresenting data, and for plans to be politically constructed to accommodate the interests of those engaged in their nominal fulfilment. Those whose jobs rest on paper fulfilments have no interest (unless pushed from below) in real fulfilment of plans, especially if, as we shall see later, their particular material interests are separately catered to. Only the democratic association of actual producers has a genuine interest in real plan fulfilment. These tendencies found expression in the Polish health services in terms of, for example, extending the stay of certain patients in hospital who no longer needed treatment to bring down the average cost of treatment of patients registered in that hospital to the norm in terms of cost per patient per day. Another example is that certain units did not provide access to diagnostic equipment for other units since they did not want to bear the cost. A further example is where construction enterprises concentrated on fulfilling easier components of their building programme than those represented by hospital construction. In so far as problems arising from these practices were identified by the Polish government, the solution was always seen in terms of improved administration rather than a political challenge to the structural aspects of the system that led to these practices (34).

Inequality of Access

The other side of this coin of bad management is that the managers can afford to be protected from its worst aspects by virtue of their privileged access to special clinics, or their ability to bribe their way past the access barriers of the state service. The following account drawn up by the Experience and Future Discussion Group (35) portrays this graphically:

> The state of the municipal and general hospitals is catastrophic: hospital wards are overcrowded, and cases of death among patients left in hospital corridors are not uncommon. Conditions created by chronic under-investment in health services fully warrant the assertion that access to treatment, hospitals, good doctors and medical equipment has become very difficult to obtain for the majority of the public. At the same time, the privileged few have special enclaves of luxury closed to people who do not belong to that group. A glaring example is the Ministry of Health clinic at Anin.
>
> Free health care for the vast majority of the population was once considered an achievement of People's Poland. But unfortunately, today the situation is completely different. Irregularities and deficiencies in health care have meant that medical treatment now requires money, quite a bit of money, as well as connections and pull. They have led to a distressing situation—if one does not bribe the nursing staff, one does not get decent attention, and if one does not bribe the doctor his care will be marginal. One now pays to get a bed in a hospital or an operation, to say nothing of medicine. Gradually the public is being divided into two categories: those who can afford proper medical care and those who cannot. If the situation does not improve substantially, the latter group will get even larger. If we are to compare incomes to the real costs of obtaining treatment by a specialist, we would probably find that at least half the public could not afford it today. This situation is alarming in the extreme.

It has been estimated (36) that the money allocated recently to create 120 places for the privileged elite at the Anin Clinic could have added 1,100 places for ordinary patients. This privileged access to special hospitals is not restricted to the managerial and bureaucratic elite, but is available also to paid officials of the Trade Union Central Committee. The TUCC has its own polytechnic "which has the advantage of referral for inpatient treatment to the Hospital of the Ministry of Internal Affairs" (18). No doubt this was one of the reasons for the rapid desertion from the official trade-union movement to Solidarity once it was formed.

Neglect of Preventive Medical Care

The lack of attention to preventive medicine in Poland involves the continuation of dangerous working processes, the

pollution of the atmosphere and rivers, and the production of carcinogenic foods. On the first point, a Solidarity spokesman (32) stated:

> Health and safety has been one of our greatest problems for many years. The health and safety representatives of the old unions were too close to management. The health and safety councils were worthless. Production had to be kept up at all costs.

Something of the consequences of this situation can be judged by an analysis of work days lost in Poland. In 1974, accidents, poisoning, occupational and nonoccupational injuries were reported to be the cause of 20 per cent of all days lost from work (18). On the question of atmospheric pollution, the Experience and Future Discussion Group (35) commented:

> Industrial enterprises emitted 3,439 million tons of gases [in 1977] into the atmosphere but trapped only 667,000 tons. If one adds to this that the majority of stack filters are almost always shut down because of the energy shortage, it must be concluded that Poland is one of the few countries in the world in which emission of industrial gases and particles into the air is not subject to control.

On the question of harmful foods, the same report (35) asserts that "25 per cent of the food products on sale have characteristics that are to some degree harmful to health, to say nothing of the many food products that are commonly adulterated by producers." Added to this must be the chronic alcoholism in Poland.

Table 3 summarises the position as far as the socialist status of its health services is concerned. Even allowing for the corrupt system of party *nomenklatura* to be classed as socialist cadre control, Poland scores still worse than its socialist neighbours. The second column indicates the extent to which the demands of and forms of struggle adopted by the Solidarity movement during its brief life, if implemented or adopted permanently, would have led to the health service becoming more genuinely socialist or even communist.

Solidarity and Medical Care Policy

Clearly a number of different political currents were present within the Solidarity movement. Those who propounded an explicit commitment to a Marxist analysis were probably in a minority, and argued with others who held a perspective of a pluralist socialism in which decentralised self-management enterprises operated to meet needs in the context of market demand. Nonetheless, it was impossible to perceive a fairly consistent line emerging from Solidarity on the question of health policy. This policy can be deduced from the reports of the Experience and Future Discussion Group (35), the text of the charter of Workers' Rights published in September 1979 (32), from the Gdansk agreement itself in August 1980 (37), and from *ad hoc* reports that emerged from Poland before the imposition of martial law in December 1981. These reports indicated that more resources should be found for health care and greater priority should be given to preventive medicine. This was usually expressed in the more limited terms of occupational safety, but a general concern for "the pillage and devastation of the natural environment" was present. In common with all other parts of the economy, the centralised planning system should be replaced by a system of workers' self-management. Medicine should be free (at least, and this reflects a certain sectionalism in the union's demands; to health service workers). Privileged access to medical care should be abolished and a fairer democratic rationing procedure for allocation to, for example, holiday homes, should be worked out. Early retirement (age 50 for women and 55 for men, or after 30 and 35 years' work, respectively) was a further health-related demand. Missing from the analysis of issues and list of demands was any real confrontation with the existing horizontal technical division of labour in medicine or with the form of technology and curative procedures used, although, in general transformed social relationships were at the heart of the methods and goals of Solidarity. The statements on the status of the medical profession were equivocal on this point. Also absent was any concern for the sexist content of medical practice. Indeed, spokespeople involved with the [illegible]n movement often expressed quite conservative views on the issues of central concern to Western socialist feminists. The Experience and Future Discussion Group (35), for example, concluded: "Family policy ought to be as solicitious of the material well being of the family as of its moral status, which requires better preparation for family life, safeguarding the stability of the family, and the efforts to control the mass spread of abortion." The October 1981 Solidarity conference resolved, in a section dealing with family policy, to urge the creation of decent living conditions for unmarried mothers in order to discourage abortions. However, by November 1981, one month before the demise of Solidarity, the *Guardian* (38) could report the existence of a Women's Forum in Warsaw which listed among its areas of concern the need to dispel stereotyped images and harmful myths about women in society, to ensure teaching about and improvement of birth control techniques, and to overcome the situation where arguments about abortion are "distinctly naive."

While a number of such general goals of medical care policy were emerging during the life of Solidarity, sectional demands were also being put forward of interest only, for example, to the workers in the health service. The demand that salaries of all health service workers be increased, and that additional payments be made for handling patients with infectious diseases, are two of these. The latter embodies the idea of hazard pay, which could be criticised from a socialist perspective.

Solidarity, in the form that gave rise to these demands, is now repressed. This, itself, is a commentary upon the nature of Polish socialism. However, even in its short life, and before it had time to work out a strategy for the successful implementation of workers' democracy in Poland, it accomplished some achievements in the health field. These included: the change of use of administrative buildings to health use, the sacking of certain incompetent and corrupt health officials, the closure of an aluminium plant in Silesia because of the effect it was having on the local environment, and the direct control by workers of the distribution of medical equipment in short supply.

Thus, while Millard (33), writing even before the demise of Solidarity, was partly correct in his interpretation that "there is no cause for optimism as the Poles struggle with the problems of years of under-funding, a cumbersome and inadequate planning system, a weak ministry, and a hierarchy of organisation and status which favour clinical specialism to the detriment of a widely conceived primary care sector unifying curative and preventive medicine", he was also partly wrong in not seeing the potential, albeit not realised, for the socialist transformation of the health service that was surely there in the ideas and programme of Solidarity.

Conclusions

This survey of medical care policy in existing socialist societies has led to one inescapable conclusion. In the economically advanced socialist societies of the Soviet Union and Eastern Europe there is very little evidence of socialist, let alone communist, forms of medical care policy. Mortality data from these countries, which are a measure of health policy as distinct from medical care policy, also compare unfavourably with data from equivalent capitalist countries.

It has been argued that the few characteristics of Eastern European medical care policy that have been described as socialist (e g, the state's role as major provider, the lower status of doctors, the employment of women in the health sector) may be attributed, for example, to the fact that these societies are dominated by a state bureaucratic or a state capitalist ruling class. Such a class is able to exercise more effective control over employment policies and levels of pay unhindered by the independent health trade unions and professions that are a factor in the West.

The accounts have not revealed a static picture of policy. There was evidence in the early days of the Russian Revolution of radical experiments in medical care policy. These seem to have given way over the years to a more orthodox capitalist-like view of what constitutes good medical care. Hungary and Poland never experienced such radical experiments. The possibility, once again for the moment repressed, of a new leap forward toward a more genuine socialist and even communist medical care and health policy in Poland has been described.

Acknowledgment—I am indebted to Julia Szalai of the Institute of Sociology, Budapest, for her detailed comments on a first draft of the section on Hungary.

Obstetrician on Trial

AFTER a 10-month suspension from all clinical and lecturing duties, obstetrician Wendy Savage is in the midst of a month-long inquiry into the management of five women during childbirth at the London Hospital. She is accused of professional incompetence, a charge usually reserved for alcoholic, drug dependent or similarly incompetent doctors.

The barrister representing the local health authority which brought the charges said the case was being presented as if it were a contest between the male establishment and the women's movement, and between the impersonal imposition of technology and a woman's freedom to decide how she gives brith. While he does not see the case in this light, the women's health movement in Britain is convinced it is precisely that.

Wendy Savage is the only obstetrician at the hospital who does home visiting for ante-natal care, and she involves women fully in decisions as to how they give birth. She is at odds with other doctors in the hospital over the politics of obstetric practice, and has fought to keep the abortion unit open when others would like to close it. There has been evidence during the inquiry that the head of obstetrics intended to try and oust her from the time he took over his job. The previous head of the department, who had set the principles and standards which Ms Savage also follows, also faced a great deal of hostility until he left.

What the local health authority probably did not expect was for the case to get such wide public attention. The inquiry has been held in public at Ms Savage's request, accompanied by constant media coverage and public discussion. Whatever the outcome, the practice of obstetrics is bound to be affected, as so many women have heard the arguments for women's choice in childbirth.

Population Policy and Situation in China

A Note

malini karkal

Chinese population policy has had two major programmes to control births: the later-longer-fewer campaign launched in the early 1970s and the one-child family campaign introduced in 1979. The immediate demographic results of these campaigns have been undoubtedly impressive, surpassing the achievements of even Japan in terms of fertility reduction.

Even so, it is unlikely that the goal of limiting the country's population to 1.2 billion in the year 2000 set by the Chinese govrnment will be achieved. Opposition to the one-child family programme has been widespread, especially since the introduction of the 'responsibility system' changing the unit of economic management from the production team to the family. The one-child family norm has also been found to clash with traditional Chinese social and cultural beliefs and practices.

The author concludes by asking whether, by seeking to drastically restrict child-bearing, the Chinese government may not be undermining its ability to foster the kind of development that it now believes to be crucial for achieving the four modernisations.

THE Chinese population was estimated to be 410 million in 1840. By 1949, when the People's Republic of China was founded, the population had grown to 540 million, showing an annual net increase of 1.19 million, or an average annual growth rate of only 0.25 per cent. High birth rate accompanied by high death rate accounted for the low growth rate of population during this pre-liberation period.

After the establishment of the People's Republic, the country' population situation showed a dramatic change. The death rate which was well above 20 per thousand (28 per thousand in 1936) dropped to 10-18 per thousand in the 1950s and then came down further to a little over 7 per thousand by 1970. This change was brought about by improvement in sanitation, public health, medical care and consequent elimination of several infectious diseases.

An even more marked change was noticed in infant mortality. The infant mortality rate (IMR), which was well over 200 per 1,000 births during the pre-liberation period, came down to 70.9 by 1957. In 1970 the urban IMR was 11 to 13 and in the rural areas it was around 30.

The birth rate continued to be high and till 1970 it was above 33 per thousand. This high birth rate coupled with the low death rate resulted in rapidly growing population. In the six years between 1966 and 1971, the population of China increased by 120 million, a figure close to that of the growth during 1840 to 1949, a period of 109 years.

During the early years of the People's Republic from 1949 to 1952, a period considered to be one of economic restoration, the rise in the natural growth of popultion was regarded as an indication of prosperity and improvement in the standard of life of the people under socialism. During this period neither abortion nor sterilisation was permitted.

Unchecked population growth and its effects on planned economic development attracted the attention of leaders and scholars and that influenced the change in Chinese population policy. In August 1953 the Government Administration Council approved "regulation of contraception and induced abortion". However, at this time neither was any definite family planning programme formulated, nor was there any education of the people for planning and limitation of births.

Family Planning Policy

A specific family planning policy was formulated in the early 1960s. In 1962 the Central Committee of the Communist Party of China and the State Council stipulated the Instructions on Conscientious Advocacy of Family Planning. These advocated controlling of births. Family planning projects were undertake in cities. Production and distribution of contraceptives was systematically planned. The urban brith rate showed a definite decline as a result. However, preoccupation with the Cultural Revolution in 1966 halted all other work, including that of family planning, thus resulting in the earlier mentioned rapid growth in population during 1966-71.

In the early 1970s a vigorous family planning movement ws launched which had the motto "later, longer and fewer". The programme advocated later marriage, longer spacing between births and fewer children. The age at marriage was meant to be 25 for men and 23 for women in rural areas and 26 for men and 24 for women in urban areas—a five-year postponment from the 20 for men and 18 for women stipulated under the Marriage Law of the early 1950s. A spacing of at least four years between births was expected. And finally the expected number of children per couple was two.

In 1978 family planning work in China entered a new stage and in 1979 the "one couple, one child" policy was put forth. The new Constitution stipulated "the control of population quantity, the improvement of population quality, and the mutual adaptation of population and socio-economic development." In keeping with this objective it was officially announced that "the State promotes family planning so that popultion growth may adapt to the plans for economic and social development ... Both husband and wife are obliged to practice family planning ... Late marriage, and late childbirth should be encouraged". Simultaneously, close kin and persons with congenital and genetic diseases were prohibited from marriage.

China now has a goal of keeping the average rate of populaton growth to 1.2 million per annum till 2000 AD. It has a policy that advocates one child per couple, strict control of second births and resolute prevention of third births. Strict action is expected against families not following this policy.

Impressive Results

Demographers point out that the achievements of the family planning programme of China are incomparable.

Upto 1970 Chinese women bore an average six children; by 1980 this number had dropped to 2.2. In 1981 and 1982 Chinese fertility showed a minor increase, but in 1984 the number of births per woman was 2. It is expected that Chinese fertility will show a further decline in the future. The previous world record holder in fertility decline, Japan, had shown a reduction of 'only' 56 per cent during a comparable period and the number of births per woman in Japan had come down from 4.5 in 1947 to 2 in 1957.

From the discussion so far it is seen that the Chinese population policy has had two large-scale programmes to control births, the later-longer-fewer campaign introduced in the early 1970s and the one-child campaign introduced in 1979. Obstacles to the implementation of the one-child family programme include the agricultural responsibility system which strengthened the motivation for large families by shifting responsibility for production from the collective to the household. Chinese culture also advocated "more sons, more blessings" and the Marriage Law of 1980 in effect lowered the age at marriage. Facing public resistance, in early 1984 the Party Central Committee reviewed its stand on fertility control and on 13th April issued a Central Document.

The Central Document reaffirmed the critical importance of family planning and re-emphasised the need to promote the one-child family in order to achieve the four modernisations, quadruple industrial and agricultural output, raise per capita income to $ 800, and hold the population at 1.2 billion by end of the century.

The immediate demographic results of the later-longer-fewer and the one-child campaigns are most readily measured by the recent rapid reduction in fertility. Bongaarts and Greenhalgh have analysed the effects of the two policies on the Chinese population. They state that as a result of the socio-economic development during the post-revolution period, the fertility of the Chinese population would have undoubtedly declined, though at a much lower rate than the observed one. These authors observed that replacement fertility (family size of two children) would have been achieved at the beginning of 21st century, instead of in the early 1980s as actually observed because of government efforts to reduce fertility.

Bongaarts and Greenhalgh estimated that without the later-longer-fewer campaign of the 1970s, the Chinese population would have growth from 0.818 billion in 1970 to 1.58 billion in 2000 and 2.41 billion in 2050. In contrast, the later-longer-fewer policy, by itself, would bring about a popultion size of 1.28 billion in 2000 and 1.81 billion in the year 2050.

Thus the implementation of the later-longer-fewer policy still leaves an eventual population size well in excess of 1.2 billion in the year 2000—the goal stipulated by the Chinese leadership. The one-child campaign is expected to solve this problem. A completely successful implementation of this policy would virtually stop growth of population. The population would reach 1.04 billion in 2000, 1.06 billion in 2025, and then fall to 917 million in 2050.

Opposition to One-Child Family Norm

Experience for the five-year period from 1980 to 1984, the period after launching of the one-child family policy, shows that in reality the population size is higher than expected. It was observed that the average number of children per woman was 2.3 and not 1. This difference was in part an effect of a change in the timing of first births that resulted from the enactment of the new Marriage Law of 1980. Though the law had raised the legal age of marriage as fixed by the Marriage Law of the early 1950s, from 18 to 20 for girls and from 20 to 22 for boys, in effect the new legal age of marriage was lower than that stipulated under the later-longer-fewer campaign. Thus the passing of the law has lowered the age of marriage in reality.

Another problem in implementation of the policy of the one-child family has been the decentralisation of the administrative responsibility for enforcing it. Individual localities are responsible for propagating and implementing the regulations. Top-down pressures for stricter enforcement combined with bottom-up demands for more children have resulted in several lacunae in the implementation of the policy. Another problem in the implementation of the policy is related to the economic incentives, such as wage supplements and priority in housing, schooling, medical care, etc. These costs are expected to be borne by the local authorities. Where the local authorities are rich, many couples sign up and as a result eat into the local funds.

Another difficulty has been that local cadres have many incentives to manipulate figures to match the officially prescribed quota whereas the higher level cadres have few incentives to uncover these errors. As a result, the data deficiencies created at the bottom of the administrative hierarchy are passed upwards, multiplying as they go up.

Also, official policies pronounced over time have had conflicting effects. The responsibility system introduced in 1980-82 shifted the unit of management and accounting from the production team (a unit of 20 to 30 households) to the family. This system also reduced the common funds of teams and increased the private wealth of families. The economic value of children has been increased and there is a strong motivation for larger families. Encouragement to small-scale enterprises and sideline activities has also motivated larger families. In the light of improved prosperity, the incentives for the one-child family have become ineffective.

In the light of the experience so far, UN estimates suggest that on an average the Chinese family is more likely to have 1.9 children by 1990-95 instead of the officially prescribed 1. The Chinese population, according to UN projections, is therefore estimated to be 1.23 billion by 2000 and 1.43 billion by 2025. These figures are higher than the target of 1.2 billion for 2000. Further, the Chinese population is expected to continue to grow after 2025, against the government's goal of a decline to 917 millon by 2050.

Social and Cultural Consequences

Sociologists predict many detrimental effects of the one-child policy in terms of its effects on intra-familial relations, gender inequality and the psychological characteristics of only children. They also opine that by fundamentally altering the basic social and economic unit, the one-child policy may tear the fabric of Chinese society in a way that uproots people's sense of their place in the world and the family's ability to take care of the old. These problems have already begun to emerge and are likely to grow more severe if the one-child policy is successfully implemented.

In the accepted system the unit of family is concerned with short-term tasks of production and consumption and the line

is concerned with long-term matters of inheritance, succession and inter-generational countinuity. An individual's place in the descent line gives him a sense of immortality and meaning to his existence. Among the basic duties of an individual to his family is to produce a son for the continuance of the family line. Since the sex-ratio at birth is around 105 boys to 100 girls, the one-child family policy will leave almost half the couples without a son and prevent the men from performing their duties to their ancestores, thereby uprooting their sense of the continuity and purpose of life. The resistance of the Chinese population to the one-child family is noticeable everywhere. Cases of famale infanticide and physical abuse of mothers who give birth to daughters have also been widely reported.

The Chinese Constitution makes its obligatory for daughters to support their parents. Acceptance of this chang at the cultural level is obviously not easy. Even in families with sons, the benefits for only-children are provided by the State or the collective work unit, rather than the parents. Thus the work units supplant parents as providers and the earlier prevalent system of the mutual obligations of generations is disturbed. This change is bound to affect the old-age support which, under the traditional system, is provided by the family.

Since late 1978 China has moved to expand the role of the private sector, not only in agriculture but also in commerce, services and industry. Since the family has proved to be the most effective production unit in such a set-up, the one-child family policy will work against the success of the role of the private sector. A family with one son is too small to be efficient and that with one daughter will face restrictions on vertical extension.

In short, by drastically restricting child-bearing, China may be limiting its productive capacity and undermining its ability to foster the kind of development that it now believes is crucial for achieving the four modernisations.

Health Care in Mozambique

padma prakash

Independent Mozambique, despite constant threats to its very existence and three severe droughts in ten years has succeeded in evolving a framework for providing rational health care. This article examines developments in health care within the revolutionary context of the government's avowed programme for constructing a socialist society.

MOZAMBIQUE is a country of five million on the south eastern coast of Africa. It became independent in 1975 after a prolonged ten-year armed struggle against the five centuries old colonial rule of Portugal. Spearheading the liberation movement was the Frente de Libertacao de Mocambique (FRELIMO), the vanguard party of the alliance between the workers and peasants. The armed struggle can be said to have begun in September 1964 with 48 guerilla fighters in four provinces of northern Mozambique. Portuguese troops numbered 70,000, half of them European. In the 10-year war, over 2,000 FRELIMO guerillas were killed.

The constitution of the Republic of Mozambique and the government programme envisage the construction of a socialist society. Within this revolutionary context and as a part of the programme of reconstruction, Mozambique has made radical changes in its health care structure which has meant a reprioritisation of health care, the introduction of new types of health personnel; more appropriate mothods of education; and a fundamental restructuring of the pharmaceuticals sector. It is the last, Mozambique's drug policy which was elicited much interest and attention by its success in bringing down the prices of drugs and making them available to the largest numbers. However, none of these have been isolated programmes—they have been proposed and implemented as an integral part of a comprehensive programme of nation-building derived from a larger political perspective of a socialist society. Also, it seems obvious that these programmes, especially relating to health care, have evolved out of the years of struggles and that experience of FRELIMO in the liberated zones has informed social policy after independence.

Before examining the health care programme in independent Mozambique, it is useful to take brief note of the political and economic developments in the country and the external pressures and internal constraints which have influenced the course of development.

In September 1975, the first FRELIMO-controlled parliament, albeit appointed by the Portuguese, was installed as the transitional government. However, even as it began to find its feet, in December it had to focus its energies on putting down an attempt by a section of the army to bring down the government. In the aftermath, President Samora Machel warned against the tendency of confusing "popular victory with permission to satisfy egotistical desires and considering luxury and depravity as a right by dint of. . . participation in the struggle."

In July 1976, the Mozambique Council of Ministers met for the first time and outlined the country's development policy and its main priorities. These were directed not at "reforming the country's old structures but at replacing them with a "new society for the benefit of the masses". The statement said: ". . . radical change (was envisaged) to place the state at the service of the masses of workers and peasants." Priority was to be given to rural areas—and national defence was to be closely linked to nation-building and resources were to be mobilised for setting up "communal villages". As regards religion, the masses would be protected against any pressure to practise religion. "The Catholic church is a reactionary organisation giving rise to counter revolutionary activities in people's democracies." Efforts were instituted to transform the FRELIMO forces into a regular army and to reorganise the police force.

One of the major features of the development policy was a series of nationalisation measures—the takeover of private schools and colleges, hospitals, clinics and all private doctors' and lawyers' practices. The export of cashew nuts—45 per cent of world output—was placed under government control. All buildings and land were taken over. "Certain individuals" were to work for three years without payment. Everyone had to pay one day's salary each month into a "solidarity bank" to be used to help "oppressed people of the world", particularly Nambia, Rhodesia and South Africa. With the announcement of nationalisation measures however, relations with Portugal deteriorated and agreements of co-operation between the two countries remained suspended.

While 60,000 Mozambique refugees who had fled to Tanzania were invited to return, new citizenship legislation denied residence to any foreigner who had satyed outside the country for more than 90 days. Thousands of Portugese who had fled the country after racial clashes in 1974 lost the right to return.

The liberation of Mozambique "radically altered the balance of forces in favour of African nationalists." There was an intensification of guerilla warfare against the White minority regime in Rhodesia by African nationals based in Mozambique. The border between the two countries was closed and Mozambique, following UN imposed sanctions including the confiscation of Rhodesian property in Mozambique. This resulted in a closure of Rhodesia's rail links with the ports Beira and Maputo. It also cut Rhodesia's food supplies to Mozambique. Mozambique appealed to the UN Security Council for an aid of $ 1,000,000 a year to meet the financial consequences of the decision to apply sanctions against Rhodesia. Sweden increased its aid to Mozambique by 40 per cent. UK supported the decision; Uganda and Zambia saw Mozambique's decision as an "act of courage and commitment to the cause of peace and justice for all mankind" and urged support for Mozambique until victory was won by Zimbabwe. Mozambique's losses in customs and port dues were estimated at £ 17,000,000 a year and about 86,000 Mozambians, it was feared, might be prevented from repatriating their earnings from Rhodesia.

By 1983 Mozambique was reeling under the worst ever drought in 50 years. Moreover, the tactics of the Mozambique National Resistance supported and funded by South Africa, of attacking crucial economic targets, of kidnapping foreign technicians and attacking health centres were aimed at under-

mining Mozambique's effort at creating badly-needed development facilities. Harvests were disrupted and in one district all the seven communal villages, three agricultural co-operatives and state farms were destroyed. Black marketing in food and other consumer essential were rampant and there was a rise in crime rates. Death penalty which had been abolished in 1979 was reinstated as was public flogging for robbers, rapists and black marketers, whereas the previous emphasis was on clemency. In early 1983, chloera killed 250 people and afflicted 7,000 in drought affected regions.

In April 1983 the Fourth Congress of the FRELIMO party set out some immediate goals which necessitated a change in priorities in certain areas. The Congress recognised that combating hunger was the immediate priority. It outlined agrarian reforms—small family farms, which had thus far received little help were to be supported. The development of large farms, and of agriculture co-operatives was seen as a medium-term objective. State farms were to be reorganised and consolidated instead of expanded in the following five years. Existing machinery was to be put to better use. Resources were to be diverted from large projects in industry and agriculture to small projects which would yield immediate returns. In the party politburo the emphasis shifted from military personnel to peasants and those who had been active in the liberation struggle. President Machel acknowledged that Mozambique had "erraneously developed a hostile attitude to private enterprise". A new investment code was drawn up in 1984 permitting transfer of profits and tax exemptions, etc, in certain sectors, but not in sectors such as petroleum. No private unit has been allowed to be set up in the pharmaceutical sector either.

By 1984 over 5,000,000 people had been affected by drought. Agricultural production was cut by 80 per cent in the country's 10 provinces. Lakhs of tonnes of cereals and cassava, a staple food, were lost. According to an FAO report, 100,000 died of starvation. Mozambique signed an agreement with South Africa—in return for South Africa withdrawing support to the guerilla forces of the Mozambique National Resistance, Mozambique would expel ANC activists. However, MNR continues to receive aid and clandestine support from wealthy Portugese in South Africa who number over 600,000. The MNR is now said to be operating in all the country's provinces. Only the northern most province, the cradle and stronghold of FRELIMO is free from such activity. The RNM is said to have 8,000 to 17,000 men.

Food aid has come in from East European countries as well as from USSR, Zimbabwe etc. However, Mozambique has never been self-sufficient in food. The country's annual cereal requirement is around 515,000 tonnes; local production is only 180,000 tonnes. It is against a background of these developments of the last ten years that we must view changes in health status and health care.

State of Health Care in Mozambique before Independence

Health service before independence had the characteristic features of health care under colonialism. There was economic, racial and geographic discrimination. Health facilities were predominantly urban and in White settler areas—over ⅔rds of the doctors in 1974 were in Maputo. Auxiliary diagnostic facilities were available only in three cities. Private health care was available only to a privileged urban bourgeoisie. Even within the public health care system fees were charged for services as the basis of race. Social discrimination was practised in all hospitals and services were separate to Blacks and Whites. With the emphasis on lucrative private practice, curative medicine developed to the detriment of promotive and preventive health care. Major public health programmes were taken up only sporadically or under pressure from the international community.

Typically, as elsewhere, the country was purposely kept underdeveloped—people had little access to educational or other facilities. Mozambicans were a source of cheap labour, especially in mines in other countries. Police and military authorities were used to repress progressive ideas and movements.

Medical Training

The first medical school was set up in 1963 and the first doctors graduated in 1969—the students being drawn mostly from the elite. Of 122 graduates before independence only two ever joined public service. The training which was for seven years was archaic and outmoded even by existing European standards with "excessive theorisation" and lack of practical training. What little there was of "practical" training comprised thoeretical demonstrations in the presence of patients. Basic laboratory methods were not taught, but diagnosis according to the trainers, depended upon sophisticated laboratory methods.

Pharmaceutical Industry

Mozambique had no pharmaceutical industry of its own—all drugs were imported. The six supplying countries were Portugal, Switzerland, West Germany, South Africa, France and UK. Over-invoicing, monopolies for supply of certain drugs, etc, were typically rampant. Most TNC subsidiaries showed large deficits. The government drug budget was $ US 1 milion in 1974 for a population of 9 million—average of US $ 0.11 per capita. Any drug regulation was virtually non-existent. Almost the only drug ever banned from being imported was thalidomide. Most drugs were available over the counter irrespective of their potential hazard.

Health Care in the 'Liberated Zones'

Even at the outset when the armed struggle for liberation began in 1964, the health of the fighting people was a major concern. First aid assistants and rural medical aides were trained and supported by one doctor and a few nurses. As the struggle developed into a 'popular democratic revolutionary' movement the colonial administration collapsed in many places. Invariably, the destruction of health services accompanied the withdrawing of colonial authority.

In these 'liberated zones' FRELIMO took over the responsibility of administration and building new structures to govern the areas. One of the first such services the FRELIMO was compelled to set up were health care facilities. In the beginning the liberated zones were divided into smaller administrative units. In each geographical administrative unit were built health centres and hospitals using locally available materials. A hierarchical network of health units was created. These health facilities became particular targets of attack. These units had to be built in the forests and even there they

were constantly under threat of air attacks which included napalm bombing. Education and health facilities became priority areas of concern. Ambulatory services were also provided in remote villages and also so as to protect the health structures from being detected by the colonial army—which would have been likely if obviously ill people had had to move over distances to come to hospitals.

However, the lack of adequate personnel for providing health care led to innovations and the training of local people. Political and military training of course preceded health training. Neither the militants nor any other category of worker received salaries at this stage.

Attached to these larger health units was a farm where land was worked and food produced collectively by everyone. These hospital farms played a very important role in defining a more realistic concept of health—health was associated not just with the curative process but with production and proper distribution of the right kinds of food.

Once the liberation movement gained strength and the colonial structures began to break down rapidly, constraints regarding resources and personnel became more acute. It was at this point that it was acknowledged that the preventive measures would considerably ease the pressure on curative facilities which was becoming acute due to lack of resources. Military personnel began to be trained as 'sanitary agents' and health educators. Over a million people—almost the entire population of the liberated zones—are claimed to have been immunised against small pox and cholera in this period.

Post Independence Development

The experience gained during these years was attempted to be generalised even during the phase of the transitional government. In the health sphere this was a period of confrontation in many ways between the health workers trained in the liberated zones and the university trained medical personnel. The concentration of sophisticated equipment and the razzled dazzle of medical technology often undermined the confidence of the 'new' health personnel. The attitude of the university trained doctors was both openly challenging and subversive. This group, both nationals and foreigners with its technical expertise and its class background played a significantly detrimental role.

The decision to nationalise health services was therefore an urgent necessity, especially if access to health services were to be open to all without class and race distinction. Secondly, these measures were necessary to stop "misfortune and diseases" from being "motives for exploitation". And thirdly, it was only with this decision that it became possible to "ensure the reprioritisation within health care" and ensure that the curative component of health did not mask the relevance of the socio-economic roots of ill-health of disease. Most importantly, the role played by doctors and the medical establishment was becoming a threat to the liberation movement. In nationalising the services, president Machel aptly described doctors as "social parasites" and "traitors" who dispensed medicines "like beer from a bar".

An immediate consequence of this nationalisation was an exodus of doctors from Mozambique. Only 60 doctors remained in the country by October 1975 together with about a 100 medical students and teams from North Korea, China and Bulgaria. Two years before there had been 300 doctors, almost all White. Of the teaching staff of 96 in 1973 only 14 remained—of these only five opted for Mozambican citizenship.

In 1977 a new National Health Service (NHS) was set up and a new health policy defined and evolved certain priorities:

Preventive medicine and environmental sanitation and primary health care:

Extending health coverage, the top priority being given to "communal villages" which were being constructed incorporating agricultural co-operatives, medical care, family planning, occupational health and school health programmes..

Strategies for controlling major epidemics—TB, leprosy, schistosomiasis, sleeping sickness, blindness, intestinal parasitosis with the diagnostic and prophylactic measures, defined.

Evolving a health team approach with new categories of personnel.

And most importantly, ensuring and encouraging community participation.

In 1977, to provide a basis for changes in the health structure and the redefining of personnel a pedagogical seminar was held with doctors who had been exposed to health problems in the liberated zones. It was decided that the doctors of the future were to be able to organise, lead and train a health team and act as a 'health agents' to transmit health concepts to people. A new curricula was designed to suit the purpose. A community orientation in even those subjects which had hitherto had a clinical approach was attempted. However, the leader of the health team, it was proposed, would be a 'graduate in health services' and not a 'doctor'. Specialisation would be after 2-5 years in primary health care work at the community level under supervision. He/she would then be called 'doctor in health sciences'. This concept of the 'doctor' as the leader of the health team has undergone some change. By 1981 attempts were being made to 'democratise' the decision as to who should lead the team. Also, there was provision now for horizontal mobility. But these changes aimed at diluting the rigidity of the hierarchies in the health system were being opposed vigorously by doctors.

There were other problems in bringing about such radical changes in the concepts of medical education. There was only one training school for doctors and this could not be closed. Secondly, any change in the medical education curriculum had to be such that the final qualifications would be recognised by the world medical community, as well as sceptical elements within the country.

Drugs for All

By 1978 a new pharmaceutical policy had also been adopted which has been resoundingly successful. It was directed at reinforcing national economic independence; a new pharmaceutical regulatory system was established to check the flow of drugs into the country; the NHS was to develop adequate structures for the management of drugs.

A new Pharmaceutical Service was created in 1975 under the ministry of health. A Theraputics Expert Committee (CTTE) was established as well as a central agency for medicines and medical supplies. A new law was passed compelling drug agencies to re-register their products, and firms were told that the government wished to see as few products as possible in the market. However, their compliance was entirely voluntary. In the months that followed the 'request', the number of products in the market fell from 13,000 to

2,600. It also earned the government US $ 70,000 through registration fees.

By December 1976 the CTTE had produced a new national formulary 10 months after the WHO's first report on Essential Drugs. It listed 640 items comprising 430 therapeutic substances, 20 diagnostic agents and 14 dressings. A second revision of the formulary was published in 1980 which contains only 502 items.

Prescription rules were also established, one of these being that all prescriptions were to use generic names. In 1981 a study of 4,000 prescriptions showed that 33 per cent were in accordance with the National Formulary rules. Compliance was lowest in the casualty department of the reputed Central Hospital in Maputo where there are health personnel from various countries who are not familiar with generic names.

A state corporation MEDIMOC has also been established for drug procurement by the merging of five private import companies which had been abandoned by their foreign owners. By 1981 60 per cent of the drug procurement for NHS was being handled by MEDIMOC. The new drug tender system had also accounted for a 41 per cent savings on drug purchases. In 1977 a state corporation for the retail sales of drug was also formed to ensure availability of quality drugs.

The creation of a national pharmaceutical industry is one of the objectives decided upon at the Third congress of FRELIMO in 1977. Preparatory studies are under way and a small ORS plant has been set up. The government pharmaceutical budget has gone up from US $ one million in 1974 to $ 12.5 million in 1982 accounting for 20.1 per cent of health budget from 8.1 per cent in 1974.

Conclusion

Given the fundamental conviction that everyone has a right to health, the actual realisation of the political nature of the skewed distribution of health facilities came about through FRELIMO's experience in liberated zones. Not only were health facilities the targets of the colonial army, the medical establishment's support to the government acted to strengthen anti-people measures. The denial of health care to people on the basis of class, race or sex was not a matter of chance but a deliberate measure by the colonial rulers to suppress and undermine the development of the revolutionary potential of the masses. Nationalisation of health services was an important act not only because it would ensure that health care would be more accessible to people but because the measure effectively nullified the subversive nature of a discriminatory health system and deflated the potential influence the medical establishment could wield over the masses.

However, implementing changes that strike at the social status of doctors has not been easy. Although there does not appear to be any reporting on this aspect, there is reason to believe that dissatisfaction among doctors regarding their remuneration and social status has been rising. The idea that a doctor may be just one of a health team and not its leader will take a long time to be accepted. Another feature of the health system which is not much discussed appears to be the notion of community participation. While the 'health agent' is selected by the 'community', it is not clear as to what is the extent of their participation. Mozambique's 12 million people speak 12 languages and 21 dialects and also belong to numerous different tribal groups. In such a situation only a determined effort at decentralisation can ensure that community participation will be a fact rather than a notion. Moreover, the persistent activities of the MNR have made this even more difficult to achieve.

There is also some indication that the emphasis on primary health care and the balancing of resources between it and more sophisticated hospital oriented services may be under some strain. For instance, the incidence of heart diseases which often necessitates hospital care and even surgical measures, may be rather high. In a health census of six villages the incidence of hypertension was 33 per cent in the coastal villages and 25 per cent inland. The 1,800-bed hospital in Maputo has highly sophisticated cardiac service with one of the three theatres being reserved exclusively for it. Whether this is a genuine response to health needs or a matter of 'prestige', especially considering the close association of some of these surgeons with the famous South African heart surgeons is not clear.

Another area about which little is said is the status and use of local/tribal health practices. Although some of the local doctors have been retrained as health agents, this does not mean that local practices, if they have survived at all, have been integrated. In fact, this is very unlikely. The emphasis has been on using modern preventive and promotive measures—immunisation, nutritional inputs (which has hardly got off the ground) popularising the use of latrines, use of 'clean' water, etc.

It is Mozambique's drug policy which is an unqualified success. Prices of drugs have fallen since 1977; they are being made available to an increasing proportion of the population and there has been a drastic curtailment of unnecessary and toxic drugs. The policy is under periodic review and revision. But the development of an indigenous pharmaceutical industry will bring other problems—of imports of machinery, raw materials, of wages and ultimately, of cost of drugs. These are, however, not insurmountable problems.

Even ten years after independence Mozambique has to cope with constant threats to its very existence as a state necessitating heavy military expenditure it can ill afford. It is dependent on imports of grain to feed its drought-struck population. Despite all this, it has so far succeeded in establishing a framework for the provision of rational health care to its population.

Health in Seventh Plan: Boost to Private Sector

IF recommendations of the Bhore Committee (1946) are to be considered as some kind of a bench mark for health planning, then one has to admit that all the plans for the health sector, including the latest one, have failed to live upto it. For instance, the Bhore Committee has suggested that for a population between 10,000 and 20,000 there should be a 75 bedded Primary Health Centre (PHC) which would provide coordinated preventive and curative services through doctors, public health nurses and health assistants. However, 40 years later even the 6th Five Year Plan (1980-85) target of one PHC with only seven or eight beds for a 30,000 population is far from realisation.

Implementation of health sector plans have never been taken seriously because:

a. The health sector is not considered a priority area of development by the government. Since the power base resides with the kulaks upon whom the vast rural landless and marginal and small farmers are dependent for their livelihood state resources are mainly used to strengthen the surplus appropriation capabilities of the kulaks and the bourgeosie.

b. The private health sector and the system of private practice of medicine has prevented the government from appropriating the medical and health functions by providing sops such as 'charitable hospitals' and 'voluntary hospitals' that provide 'concessional' care.

c. Government planning and programming has never taken into account what the actual requirements of the people are—people have always been 'given' what the government thinks the people want, and even that does not reach the people; and

d. The Government's obsession, under the influence of imperialist agencies, in planning and implementing health programmes, has always been with family planning.

The Seventh Five Year Plan (1985-90) in the above sense is no different from the earlier plans. It provides an even more vigorous support to the private and 'voluntary' sectors and the entire focus is on improving the management of the various programmes under the health sector. And the historical trend of a reduced proportional allocation to the health sector is continued.

In the first five year plan the health sector constituted 3.82 per cent of the total plan outlay but began to decline in each subsequent plans—3.01 per cent, 2.63 per cent, 2.12 per cent, 1.92 per cent, 1.86 per cent and 1.88 per cent. That this decline in health sector allocation is due to greater investment in population control activities is obvious from the fact that allocations to the family planning (FP) sector have increased from 0.005 per cent of total plan outlay in the first plan to 1.80 per cent in the Seventh Five Year Plan. Even the ratio proportion of allocation between FP and Health Sector has increased from 0.002 to an astounding 0.96 per cent between the First and Seventh Plans. A correlation between the percentage allocations to health and FP over the Seventh Plan periods shows a high negative correlation (Pearson's r) of -0.88. Along with the narrowing ratio gap between health and FP, this r value is a clear indication that the growth of the public health sector has been sacrificed in favour of family planning activities.

Reviewing the performance of health programmes the Seventh Plan document states that, "Most of the concerned (disease) control programmes suffer from poor management and monitoring... Health management support and supervision is an area that needs considerable strengthening."

Further, the Seventh Plan emphasises the need to provide greater support to the voluntary sector in both health and family planning. This is in keeping with the promise given in the National Health Policy of 1982, 'The policy envisages a very constructive and supportive relationship between the public and the private sectors in the area of health by providing a corrective to re-establish the position of the private sector' (India, 1985).

That the focus of the health sector will continue to be family planning activities is made clear by the following statement in the Seventh Plan document *intersectoral co-ordination and co-operation and the involvement of voluntary agencies in the programme (of the government) will be necessary in this (FP) programme to an even greater extent than in health.* Add to this the large allocation to the family planning sector of Rs 3,256.26 crore which as a proportion to the health sector allocation of Rs 3392.89 crore is the highest ever (proportion = 0.96).

Another important feature of the health sector in the Seventh Plan is its recognition of non-communicable diseases as an important area for development; "Development of specialities and superspecialities will need to be pursued, with proper attention to regional distribution." Whereas with regard to the highly prevalent communicable diseases, they mainly affect the deprived masses, the Seventh Plan document stops at saying that the programmes have failed in achieving their targets and therefore only better management is the answer.

Related to the focus of diseases of the priviledged few the plan recommends a special priority to new medical technology, especially biotechnology and electronics. The special attention that AIDS, cancer and coronary heart diseases are receiving and the current boom of the diagnostic industry is a clear indication

where the health sector priorities lie.

Finally, it is interesting to note that the health sector plan does not comment on the drug industry on which the national disease control programmes are greately dependent. Drugs and pharmaceuticals are left to the Industries sector where no mention of essential drugs is made. Even with the major communicable diseases being national programmes, (leprosy, tuberculosis, malaria, blindness, filariasis, goitre and guinea worm infestation) there is no concern in the plan document about shortages of these essential drugs which are imported in bulk inspite of a sophisticated pharmaceutical industry in India.

Local Health Traditions and Primary Health Care

LOCAL health traditions are primarily based in the use of local flora, fauna and minerals. A very significant aspect of the local health traditions and its practitioners is their self-reliant nature. These traditions are of an entirely autonomous character rooted in a community's social traditions of knowledge and supported from within the community. No government or any other agency has ever been required to offer any direct support to these traditions of health-care. A seven-day meeting was held in November 1985 at Karjat, Maharashtra, to discuss ways for strengthening local health traditions related to primary health care. People from 30 rural organisations interested and active in the community health field from Kerala, Tamilnadu, Andhra, Karnataka, UP, Bihar, MP and Maharashtra attended the meeting.

Most of the groups previously carried the prejudiced impression that local health cultures were based on blind belief or purely an empirical experience because this is the false propaganda that western science had spread about indigenous knowledge. In fact, to date not a single serious evaluation exists of the strengths and weaknesses of any local health culture in any part of India, despite the fact that millions of Indians still subscribe to traditional health practices. There is evidence to establish that Ayurveda is the scientific mainstream behind all the local folk and tribal health traditions in India. There appears to be a symbiotic relationship between the two. The mainstream drawing strength from the particular experiences of numerous local streams and the local streams in turn being enriched through interaction with the mainstream.

The meeting observed that a sort of cultural genocide (which began about 200 years ago) on the local health culture of thousands of village communities is yet taking place in independent India. This is inspired by the Western ethno-centric outlook of the Indian scientific establishment. Ironically although local health traditions are in fact more comprehensive in scope and cover all and more than the usual elements that are expected from the 'primary health care' programmes of the government, these local traditions are being totally ignored and suppressed.

When one talks about the scientific temper in India, we usually impose an essentially European 'mainstream' cultural tradition (Europe also had non-mainstream scientific traditions, e.g., based on writings of Goethe) on the Indian people. There is in fact also an indigenous scientific temper that still persists amongst millions of our rural folks and amongst the tribals. This indigenous scientific temper is indeed very different in content and form from the European one and it is only cultural arrogance and intolerance that may make us blind to its value.

Strengths and Weakness of Local Health Traditions

In the Karjat tribal block over the last 5 years a detailed documentation of the local health tradition is being undertaken. Similar work is being conducted in other parts of Maharashtra (Nanded district, Gadchiroli and Poona district), as also in Warangal in AP, Ranchi in Bihar and Coimbatore district in Tamil Nadu.

Although the local traditions are comprehensive in their 'scope' they undoubtedly reveal several weaknesses in treatment procedures and diagnosis when subjected to critical evaluation by the science of Ayurveda. Although with regard to the use of local herbs the local tradition has an amazing knowledge of local flora its ecology, identification, types, etc, knowledge about properties of plants is incomplete. There are perhaps several reasons which may explain how and why these weaknesses have set in—in the first place the local traditions are 'oral' traditions of knowledge and in the natural course of things oral traditions the world over have been found to decay over 'time'. They need to be revitalised from time to time in order to regain 'vigour'. An external reason for the current decay of local traditions is the derision, neglect and oppression they have suffered due to the intolerant attitude of the western scientific tradition towards these practices. A third reason is the break of active links during the last few centuries with mainstream science of ayurveda. This has resulted in mutual losses. These weaknesses however do not detract from the comprehensiveness of the local traditions, nor reduce their potential for making the community self-reliant in its primary health care needs.

Workshop Report

Documentation of Local Flora: On the first day participants accompanied by the botanists from 'Maharashtra Association for Cultivation of Science' and AVR Educational Trust, Coimbatore, visited the local forest and collected 25 illustrative specimens of locally used medicinal plants. There were detailed discussions on the basic botanical notes that should be taken about each plant and what parts of a plant are essential to collect for purposes of identification and how plants can be pressed and dried and put into herbarium sheets.

On the same day, in the evening there was an introductory talk on Dravya-Guna Shastra which is

about the theory and methods by which Ayurveda establishes the properties of plants and predicts their effects on the human body.

The next two days of the workshop were spent in observing and participating in the preparation of medicines by processing plants in various ways. Nine different basic techniques of processing of plants were demonstrated *viz*, kadha, swaras, tel, ark, ghanwati, shar, satv, malam and choorna.

Documenting Local Health Care Practices: Two days were spent on understanding some of the strengths and weaknesses of the local traditions regarding (1) mother and child care (2) home remedies and (3) the treatment of common ailments and first aid. The ADS presented participants with a copy of the type of questionnaire they had used to study the local traditions which could be used as general model for similar studies elsewhere—but the detailed format may vary from region to region.

Food and Nutrition: The sixth day was spent in discussion on two subjects, *viz*. the basic natural principles of ayurveda and the ayurvedic theory of nutrition. As a result of this western ethnocentric view, today under the banner of spreading science to villages, very many sound nutritional practices of villagers are being destroyed and undermined because of lack of understanding of the Indian nutritional science.

On the seventh day there was discussion around the historical analysis of the colonisation of the Indian mind by the mainstream west—a process which began 200 years ago and continues even today under a political leadership which wants India to 'catch up with the west' in the 21st century. A view was put forward that perhaps it was at a historical moment of weakness that the Indian civilisation accepted the cultural and inellectual traditions of their colonisers and that this acceptance was not based on any critical process of evaluation of the western traditions.

It was unanimously resolved to form an informal national committee, the Lok Swasthya Parampara Samvardhan Samiti for strengthening local health cultures. The AVR ayurvedic trust, Coimbatore, agreed to act as the secretary of the committee.

For further information please contact Dr. G.G. Gangadharan, Lok Swasthya Parampara Samvardhan Samiti, Pathanjalipuri P.O., Thadagam, Coimbatore – 641 108.

Drug Multinationals and WHO

THE unofficial, information links between multinational corporations and some UN agencies have long been debated. The ICP (Industry Co-operative Programme) within the FAO was a prime example, and had to be dismantled once the links were discovered by action groups. On the other hand, the WHO prescription for a rational drug policy is well known, has been recommended for *all* countries, developed and underdeveloped and is often adduced as proof of the WHO's neutrality. Its prime principal contribution has been the selection of a list of essential drugs numbering 250, and which the WHO has suggested is more than adequate for a population's basic health programmes, a list, of course, that has not enamoured the WHO to the drug multinationals.

The new drug policy has reversed many of the offensive features of the drug scene available in most third world countries including India, where the production of a large number of inessential and harmful drugs has led to a decline in the production of basic and essential drugs. Despite what critics of the Bangladesh drug policy, instigated by drug MNCs have claimed, the new policy has led to an increase in the production of essential drugs, has reduced prices and improved drug investment by the very same companies who have tried to criticise the policy in the past.

Concerned about these positive developments and their possible impact on other third world countries, the drug MNC have now recruited a Sri Lankan lawyer to write a book attacking the policy. The book is entitled, *The Public Health and Economic Dimensions of the New Drug Policy of Bangladesh,* is written by D C Jayasuriya, and sponsored by the apex organisation of drug multinationals worldwide: The International Federation of Pharmaceutical Manufacturer's Association.

Jayasuriya uses his former WHO consultancy status to give his 'evaluation' of the Bangladesh drug policy some measure of legitimacy, which it, being a sponsored study, readily lacks. The document is being passed about as a 'WHO document on the Bangladesh Drug Policy'.

More interesting is the fact that the document has been sent to the personal addresses of Drug Controllers, Health Ministers and other influential administrators in all Third World countries. This has not however been done in Bangladesh, where a whisper campaign instead has been let loose to say that the "WHO has published a document against the drug policy." The WHO is obviously aware of these developments and has yet not distanced itself officially from the Jayasuriya 'evaluation'.

The requisition of a Third World individual to attack a socially useful policy from another Third World country, at the obvious behest of drug MNCs is deeply disturbing. No action has been taken against Jayasuriya despite the fact that these developments have been brought to the attention of the Director General of the WHO, Dr Halfdan Mahler himself.

We believe that part of the reasons for the incapacity or unwillingness of the WHO to act firmly is rooted in the financial indebtedness of the WHO to countries like the USA. For example, it took a full two years before Dr Halfdan Mahler himself publicly approved the Bangladesh drug policy. There is need for more unambiguous approach. If necessary, the WHO should seriously consider alternative sources of funds to act more forcefully in the interests of all drug consumers.

Even now it is ironic that the WHO is unwilling to act when it sees an attack on a drug policy that is based on the recommendations of the organisation itself.

Homoeopathy

b k sinha

Homeopathy, the author contends, goes well with the holistic health movement and holds the promise of making necessary medicines available to all.

HOMOEOPATHY is today's medicine because it offers a way out from the situation the people in need of medicine face. One of these problems is the cost. Treatment has become terribly costly, forcing an overwhelming majority of people to suffer helplessly or succumb to diseases. Homoeopathic treatment is much cheaper. The manufacture of these drugs does not involve the kind of technology which would lead to monopoly and consequently to cost escalation. Besides, the action of homoeopathic drugs does not depend on the quantity of drugs administered but on potency and higher the potency, the less there is of the medicinal matter in it. And one of its basic principles is to keep the dose of the medicine to the minimum.

Homoeopaths prescribe drugs on totality of symptoms. This saves the ordeal of going through surgical operations in most cases. Its principles for treating a group of symptoms have been tried and tested in the last 175 years and its structure is such that new information can continually be incorporated into the existing body of knowledge. And the logic behind these principles is such that it avoids logical contradictions of other systems of treatment by elevating the concepts of health, disease and cure to a level where these contradictions do not operate.

In all societies and in all ages, human beings face concrete problems and is oppressed by them. Consequently, they endeavour to solve them and to understand them. The understanding of the problem is crucially dependant on the tools that they possess including the power of abstraction. Both these tools and power of abstraction crucially depend on the state of development of the society. Within this limitation, there is yet another limitation: that of the class nature of the problems and following from it the class nature of the solution advanced. If the problem of study stems from the class needs of the ruling class and the solution to it does not question the beliefs and ideas justifying the existence and the privileges of the ruling class, the individual studying these problems and advancing solutions get support, recognition and glory from the ruling class. If these bases are questioned, such individuals incur the wrath of the ruling classes and are dealt with accordingly. If the questions studied and the answers advanced are such as do not interest the ruling classes, howsoever beneficial they may be to the advancement of the society as a whole, those are simply ignored till a class comes to recognise their usefulness, either as the ruling class of the day or as a class in struggle against the ruling class for supremacy and power. It goes without saying that societies whose ruling class in certain periods of time either suppresses such studies and solutions of the problems or ignores them is condemned to stagnate and degenerate. Historically, we see two types of development that take place in societies condemned in this way, depending upon the level of development of the society in question. If because of the development, such a class has emerged in the society which could withstand persecution, the task of developing society drives many individuals to take up such study notwithstanding the persecutions. The ruling class is then replaced by another ruling class which enables the society to develop further. If, again because of the level of development of the society, such a class has not emerged which could withstand persecution, it leads to various kinds of distortions in the existing body of knowledge of the society and to an ever increasing difficulty in procuring the means of life from surroundings, to maintain its existence and that of the ruling class. If the natural surrounding of such a society is bountiful, it manages to keep itself alive despite its stagnation and consequent distortions in its consciousness; if not, such societies must perish leaving the marks of their existence on history.

An individual's response to the problems faced has elements of both universality and particularity. Universality, because the basic problem sought to be solved and the tools of enquiry at a specific stage of development are universal. Particularly, because the answers to these problems are in terms of what is available either from nature or from what is inherited from previous generations. Hence the element of particularity is to a minimum level in primitive societies. It is for this reason that different societies existing at different points of time and space and drawing the necessary means of life in a similar method and ways tend to enquire into the problems they face in similar ways and arrive at similar answers. At a certain point of time and space, if there is a change in a society's methods and ways of procuring the necessary means of life, its ideas about the problem it faces, its tools of enquiry and the answers it advances for its solution too change, in the main. But societies where this change has not taken place continue to live in the old ways with their old ideas.

Health and freedom from illness is one of the most basic human needs. Primitive response to this need is universally magical. It could not but be so. For it was a long time before human societies could even pose the problem properly and did not possess even the elementary tools to enquire into the problem. Later, as experience accumulated abstractions of experience as beliefs and theories were put forward. Hence we see the sprouting of different systems of treatment in different societies. Some of these systems have survived to this day although they could not remain unaffected by the development of science and logic either in their own society or in other societies they came in contact with.

Besides, the human endeavour to fulfill health needs and discover cures for illness directs enquiries into various aspects of the problem including the human body, cause of disease, effects of drugs, hygiene, etc. The answers to all these questions must be limited by the tools available and must at the same time reflect current beliefs including taboos. Besides, the less developed the tools, the greater the grip of beliefs and taboos. On the other hand, the greater the stakes behind these beliefs and taboos, the greater the force with which they are defended. Hence any of the systems of treatment needs to be evaluated for its objectivity, not on the basis of its own 'theories' and beliefs, not on particulars, but on the basis

of science, on the basis of what is abstracted from the particulars, the universal.

If we look into the systems of treatment practised in ancient civilisations like the one in India (Ayurveda), China and Greece we find that each identifies the cause of disease differently. While Ayurveda identifies *vayu, pitta,* and *kapha* as three doshas, a disordered state of which afflicts the body with diseases of various kinds, the Chinese system identifies the balance two opposing principles—the *yang* and the *ying*—and an imbalance, therefore, meant diseases. Similarly the Greeks believed that when the four humours—blood, phlegm, yellow bile and black bile—were in balance, there was a state of health; when not, diseases resulted. Rome, after conquering Greece, based its system on Greek system but Roman physicians developed the system immensely.

Even a cursory glance at their history reveals that the inner vitality of these systems which propelled them to acquire new experience and propound theories is subsequently plagued. The loss of vitality of these systems reflects the loss of vitality of the civilisation and societies which gave rise to these systems. A period of stagnation followed. The reason is simple: the then ruling class in all these societies had become parasitical in course of time and therefore its relation with scientific enquiry had became antagonistic. Consequently, scientific enquiry was discouraged and scientists were persecuted. This is brilliantly underlined by D. P. Chattopadhyaya in his works (Chattopadhyaya, 1976, 1977).

European historiography describes the period 600–1400 A.D. as the Dark Ages of medicine. Dissection of the human body was prohibited. "The history of Europe in those days is the history of typhus and plague, of rats, lice and men... The lack of scientific knowledge promoted superstition in medicine. Saints were invoked for the curing of disease—St. Clare for sore eyes, St. Sebastian for plague, St. Appolonia for toothache, etc (Nelson, 1927).

Science having been tabooed elsewhere, Arabia came forward to take science and medicine to new heights. They preserved Greco-Roman wisdom, further developed it and enriched it with new drugs. Their contribution in the field of pharmacology is great. The system of medicine they gave rise to is known popularly as Unani system. But later, their civilisation and along with it their medicine fell into a period of stagnation much as in other societies and for mostly the same reasons.

Thanks to the maturing of merchant and manufacturing capital in some societies, not only the persecution of scientists came to an end but they began to receive state encouragement. Individuals came forward in many fields of activities including science, logic, medicine and so on, who could be compared with Columbus in their fields. Beginning with Fractorius and Paracelsus, a galaxy of physicians shed new light on various aspects of the human body and diseases. Newton and Bacon widened the horizon of human thought to an unprecedented level. Further development of knowledge came to depend crucially on the development of a logic and based on it the classification of the existing knowledge. In the field of zoology, it was taken up by Cuvier and in the field of pathology by his contemporary, Hahnemann, the founder of homoeopathic system of treatment. But Hahnemann did much more than attempt to classify diseases—he developed a logic which put forward different concepts in relation to diseases, cause of the diseases, medicines and the way medicines act and advanced several hypotheses which were later substantiated by different branches of science.

In Hahnemann's days therapeutic practice was appaling. Stuart Close says:

> Ideas which now seem absurd were then matters of the most serious moment, and in their practical working out often became tragical. Blood letting, the outgrowth of one of these false theories affords a good example. The celebrated Bouvard, physician to Louis XIII, ordered his royal patient forty seven bleedings, two hundred and fifteen empties or purgatives and three hundred and twelve clysters during the period of one year ... the death of our own George Washington was undoubtedly caused by the repeated blood-letting to which he was subjected. He was almost completely exsanguinated (Close, 1979, pp 28-29).

Nature of Scientific Enquiry

Science studies nature in general and within this universality, the different aspects of nature, the particularities. All scientific enquiry reflects nature more deeply, truly and completely. But what exists in nature is matter in motion. Hence what science studies is different forms of matter in motion, scientific judgements and concepts relate to it and therefore are needed to be placed at different levels.

To illustrate the point: The simplest form of motion is change of place—mechanical motion. But there is no such thing as motion of a single body although motion towards a centre common to many bodies can be treated as such. But as soon as a single body moves in a direction other than towards the centre, the laws of falling to which it was subject, undergo modifications:-

a. As laws of trajectories and lead to reciprocal motion of several bodies, planetary motion, equilibrium in motion itself. But the real result of this kind of motion is ultimately the contact of moving bodies—they fall into one another.

b. As laws of bodies in contact—ordinary mechanics, livers, inclined plane, etc. But the effect of the contact is not exhausted by these. Contact is manifested directly in two forms: friction and impact. Both have the property that at certain degree of intensity and under certain conditions, they produce new effects like heat, sound, electricity... no longer mechanical effects.

c. As science of these forms of motion—physics. It establishes the fact that under certain conditions, they pass into one another and at certain degree of intensity which varies according to the different bodies set in motion produce effects which transcend physics, changing the internal structure of the bodies—chemical effects.

d. As science of chemical nature and internal structure of bodies. Its task becomes to prepare these substances artificially and it subsequently prepares the ground for dialectical transition to the organic sciences... (Marx and Engels, 1953, pp 342-43).

We thus see that all these branches of science study the particularity of contradiction and are differentiated on this very basis. These contradictions are rooted in the objective world and are independent of human will. And human thinking is a subjective relfection of the objective world. But human thought may or may not reflect the objective world correctly. The contradiction between a correct and an incorrect reflection of the same thing in nature gives rise to another type of contradiction—logical contradiction. Appearance of a logical contradiction in human thinking means that the thought is not correct and development of thinking depends

upon its solution. But for this, it must be separated from dialectical contradictions—the contradictions existing independently in nature. But given the nature of human knowledge and the way it has advanced, logical contradictions too are mistakenly treated as dialectical contradictions and pose difficulties for separating the two. Besides, it can be separated only on the basis of practice. But the word practice has to be understood clearly—it is different from what can be termed as 'naive practicality'. For practice to be correct, it has to be guided by theory and the latter must correspond to the level at which the contradiction operates.

Consider an example. Euclidean geometry grew out of practical activities spanning centuries. Its axioms and theorems are still found correct and serve our needs. It served Newton's needs as well when he was formulating his laws of gravitation. Newton's laws of gravitation are one of the greatest triumphs of science. But he could only describe gravitation, he could not explain it; limited as he was by the level of science of his day. Explaining it would require on the one hand, such fundamental advances as the development of the concept of fields, the creation of electrodynamics and the theory of relativity. It would also require, on the other hand, a deeper approach to natural science, its methods and problems. But when one begins to explain gravitation, one simultaneously begins to see the contradiction inherent in both Euclidean geometry and Newtonian mechanics. This of course, does not mean that Euclidean geometry or Newtonian mechanics are wrong; they are very much correct within their own limits. The confusion arises only when their limits are violated.

Hahnemann's Contributions

Hahnemann lived in an age in which he could ask questions and provide answers only in the hypothetical form; he could not back up his hypothesis with exact experiments, nor could he express himself in the exact language and terms of science. The problem was compounded for him as he enquired into complex subjects like health, disease, cure, action of drugs, etc. He could bank only on his power of observation and abstraction and could draw but little from his predecessors. The competence with which he founded his therapy is amazing. And in so doing, he gave a new interpretation of these concepts, applied some of the known principles in a different way and developed his system of cure.

It was Hahnemann who gave the name allopathy to the system which was practised in his time. In his time, quite like the present, treatment generally proceeded on the principle that a disease or a symptom of disease is cured by using a medicine that opposes the symptom, either by direct suppression or by inducing a reaction leading to its suppression. Even the descriptive terms for drugs with prefix "anti" indicate the principle on which they are prescribed. He opposed this principle and called his system homoeopathy. The basic principle of homoeopathy is stated in a phrase: "Similia similibus curentur" or "Like shall be treated by like".

Hahnemann was not the first to propound this idea. It had been expressed by thinkers and scientists from ancient times. He acknowledged his debt to Hippocrates, in whose writing the principle of "like cures like" appears. In ancient Indian philosophy we find a similar reasoning advanced by Uddalak Aruni in Chandogya Upanishad, "The essential nature of the cause is to be inferred by the essential nature of the effect" (Chattopadhyaya, 1976, p 477). But this principle in itself could not have taken Hahnemann beyond Hippocrates. As it constituted a part of the complex whole he was reasoning, it propelled him to go further and devise suitable means for its application.

Allopathy and other systems of medicine believe that the cause of the disease must be diagnosed before to determine proper treatment. But knowledge of the cause of the disease depends on the level of theory and the available tools of investigation. A further deepening of knowledge must therefore invalidate old therapeutic practice which is only logical and sound. But the cause of the disease is too complex. Disease, like health, is influenced by a number of factors in complex combinations. This constitutes a logical contradiction and leads to unsound therapeutic practice. James Krauss says:

> It is impossible to know all the antecedents causative of disease consequents. ... How then shall we remove or palliate these effects by medical substances? Here, Hahnemann steps in to say, 'remove the effects and you remove the disease'. We must apply medicinal substances on the basis of knowledge of their actual effects which we have ascertained and know. Disease effects are removed by the application of medicines having corresponding medicinal effects. Scientific comparison of disease effects and medicinal effects for application leads to the diagnostic inferences of scientific medicine, makes scientific medicine possible (Krauss, 1979, p 9).

Besides, Hahnemann had observed the opposite action of large and small doses of medicine. Ipecac in large doses caused nausea and vomiting and in small doses, under certain condition, cured it. This held good for a number of drugs then in use. This observation led him on the one hand to anticipate what was later discovered and formulated by the Arndt-Schulz law, an allopathic rule formulated towards the end of the nineteenth century. On the other hand it led him to propound the theory of potentisation or dynamisation.

Potentisation is a process of dilution and vigorous succession at each stage of dilution. If the original medicinal substance is soluble in ethyl alcohol, the starting point is a concentrated solution called mother tincture (O). If it is not, then it is triturated with 99 parts (in centisimal and decimal scales of dilution respectively) of milk sugar. After this initial trituration, one part of this is again triturated with 99 or 9 parts of milk sugar depending upon the scale. After third trituration, he observed, the medicinal substance becomes soluble in alcohol. [Triturations therefore anticipate the development of colloid chemistry.] It is then treated like soluble substances and further diluted to reach higher potencies.

Dalton's atomic theory and Avagadro's hypothesis were known in Hahnemann's days. The atom was not considered to be divisible by the former and according to the latter, one gram molecular weight of any compound or element contained approximately 6×10^{23} molecules. Therefore, if one gram molecular weight of any substance, say for example 48.46 gram of sodium chloride (natrum muriaticum) is dissolved in 99 parts of water then the solution will contain 6×10^{23} molecules. If one part of this solution is diluted in 99 parts of water then the solution would contain 6×10^{21} molecules assuming that the solution is thoroughly mixed. Second dilution will leave 6×10^{19} molecules. If we go on then a stage will be reached when the number of molecules present in the solution will be 6×10^{1}. At this point if we take a hundredth part of the solution then the number of molecules will be 6×10^{-1} or 0.6. It means that beyond 12th.

centesimal or 24th decimal potentisation, not even a single molecule of the original substance is there in the medicine. But the more commonly used medicines are 30th and beyond.

Hahnemann was aware of this paradox. He advanced the reasoning that the process of dilution and succession released a "spirit like power". Stuart Close adds, ". . . homoeopathic potentiation (potentisation) is nothing more or less than a physical process at which the dynamic energy, latent in crude substances, is liberated, developed and modified for use as medicines" (Close, 1979, p 219).

Hahnemann by arguing that removal of symptoms itself meant cure from the disease and by treating the question of health, disease, and power of medicine to cure at a dynamic plane, elevates them to a plane where the contradiction inherent in other systems of treatment does not operate. This in itself is a great advance in science and the applied science of medicine.

Homoeopathy and Its Detractors

Homoeopaths and homoeopathic treatment are more widespread than is normally estimated. England is an important centre for homoeopathic teaching and practice and homoeopathic doctors are part of the National Health Service. According to an official estimate in 1972, there were more than 72,000 registered homoeopaths in India. Other commonwealth countries like Australia, New Zealand and Canada have quite a significant number of homoeopaths. It is also taught and practised in the USA, France, Germany, Switzerland and Holland. This in itself should be sufficient to silence those who ridicule the homoeopathic system of treatment by saying that there is no medicinal substance in the drugs.

They can convince themselves by the reasoning advanced by Bernard and Stephenson. In an article written in 1967 they proposed that through the process of dilution and succession, the active substance acts as a template, communicating a field to the solvent through the formation of polymer chains (gaint molecular aggregates) in the solvent. The three dimensional structure of such polymers would be specific to each individual solute. Once the structural informational content of the solute has been transmitted to the solvent through the formation of the polymer chains, the solute need no longer be present for the solvent to communicate that information to the human organism (Bernard and Stephenson, 1967, pp 277-86).

Mathew Hubbard pointed out in an article in 1977 that when Avagadro formulated his law, matter was not believed to be visible beyond the level of the atom. Now, of course, we have identified subatomic particles, and one contemporary model defines atoms as ordered waves of energy. Thus when we study the phenomena associated with apparently material substances, we are no longer restricted to the realm of matter; matter and energy are interchangeable and are constantly being transformed from one form to the other (according to the first law of thermodynamics, as electrons jump from one orbit to another around the nucleus of the atom, radiation is released, which can be measured on a spectroscope). Each chemical element has its own spectroscopic "fingerprint", which is produced by this characteristic pattern of radiation. He proposed that the energy released from such molecules of matter must permeate an entire solution; thus, even if there is not a single atom of the original substance present in a highly diluted solution, the energy associated with this subatomic activity should be present in the solvent (Hubbard, 1977, pp 433-36).

The above two tentative approaches to the explanation of the activity of high potencies have some implications that can be tested in the laboratory. In a series experiments in the 1950s, A Gay and J Boiron demonstrated measurable differences between the capacitances (dielectric constants) of distilled water and of sodium chloride dissolved in distilled water and carried through stages of dilution upto 10^{-605}. Also, in 1931, Paterson and Boyd showed that the Schick test, conventionally used to determine the presence or absence of immunity to diphtheria, can be altered through the administration of high potencies of either alum precipitated toxoid—used by the allopaths in material doses to induce immunity—or of Diphtherinum, a nosode prepared from a diphtheritic membrane. There are many more studies of experiments to prove the effect of high potency drugs. Weiner and Goss cite a few examples in their book (Weiner and Goss, 1982, pp 129-30).

Another group of detractors allege that since homoeopathy is solely concerned with symptoms, it ignores even such cause(s) of the disease that modern science so powerfully establishes, like bacteria. Some go further and argue that even after the symptoms are removed as a result of homoeopathic treatment, the cause remains and therefore the symptoms again reappear. Yet another criticisms is that since it treats individual patients and prescribes different drugs to different persons suffering from similar symptoms, it is not suitable in epidemic conditions. A surprising thing about such criticism is that they are levelled not by uninformed persons but by highly informed ones, by 'experts'.

Such criticisms spring from a profound ignorance of Hahnemann's teachings and subsequent developments in other fields of knowledge and science. In section 31 of *Organon*, Hahnemann says: "The inimical forces, partly psychial, partly physical to which our terrestrial existence is exposed, which are termed morbific noxious agents, do not possess the power of morbidly deranging the health of man unconditionally, but we are made ill by them only when our organism is sufficiently deposed and susceptible to the attack of the morbific cause. . ."

We thus see that Hahnemann not only identifies "morbific noxious agents" but also explains the reason because of which not every one succumbs to bacteria though all may be equally exposed to them. It would be interesting to note that he recognised the presence of bacteria and attributed to these animal forms, too minute for the eyes to see, many forms of epidemic and acute illnesses. He announced his deductions in 1818, more than 60 years before Koch isolated the tubercle bacillus (Roberts, 1979, pp 180-81).

Stuart Close says:

> The real cause (of the disease) is the whole of these antecedents, and we have no right, philosophically speaking, to give the name of the cause to one of them, exclusively of the others.

Also,

> Brilliant and successful as have been the attainments of bacteriologists in creating a new science of sanitary engineering, they have failed and must continue to fail, to establish bacteriology as the basis of a therapeutics.

Further,

> In cholera, for example, admitting the existence and presence of the bacilli as one causative factor, we still have to reckon with sanitary, atmospheric and telluric conditions; with economic and

social conditions and habits of life, with means and modes of transportation and intercommunication between individuals and communities; with individual physical, mental and emotional states, etc., all of which are essential factors, in some combination, in determining and modifying the susceptibility of individuals to the bacilli; for without some combination of these factors, the bacilli is impotent and the disease would never occur (Close, 1979, pp 268-69).

We thus see that homoeopathy is closer to the modern concept of health care and preventive medicine than other systems of treatment including allopathy.

Homoeopathic treatment has been successful in epidemics even during the lifetime of Hahnemann. Weiner and Goss give a detailed report of a survey conducted in England to determine the effectiveness of a homoeopathic nosode, Influenzinum. This holds good for the diseases caused by the virus also. Weiner and Goss add a speculative note:

> There is a widespread concern about the dangers of the research in bacteriological warfare; scientists and the lay people alike portray the possible disastrous consequences of the escape of virulent organisms that have been specifically bred to resist chemotherapy. Mysterious illnesses, such as 'legionnaire's disease' have also aroused public interest. The allopathic response to legionnaire's disease was to search for an etiologic agent in order to determine the proper medicine to eradicate the hypothesised 'bacteria' responsible. In theory, homoeopathic treatment could yield impressive result in such instances for two reasons: (1) both situations have the characteristics of epidemics, hence a single remedy or a group of remedies could be determined for each particular epidemic as the proper treatment in the majority of cases; and (2) since homoeopathy selects the remedy on the basis of symptom alone, identification of the organism involved would not be necessary, nor it would be necessary to develop a chemotherapeutic agent that had the specific effect of eradicating that organism.

Underlying the specific precepts of homoeopathy there is a vitalistic principle that is clearly spelt out in *Organon* (sections 9 to 14). Section 15 visualises the "affection of the morbidly deranged spirit-like dynamis (vital force)" and "the totality of the outwardly cognizable symptoms produced by it in the organism and representing the existing malady, constitute a whole." This vitalistic principle at the heart of the homoeopathic doctrine and dialectical method of its application distinguishes it from allopathy and other systems of treatment.

Hahnemann believed that diseases entered the body in the form of miasms— subtle, imperceptible substances as "imperceptible as the vital force itself". He divided all diseases into two broad categories: (1) Acute disease or actue miasm: These are rapid in development and have a definite course consisting of three phases: (a) a prodromal period of onset; (b) a period of progress and (c) a period of decline. The vital force is generally able of curing itself in such cases provided the attack on the organism is not so violent as to cause death. (2) Chronic diseases or chronic miasm: There is again a prodromal period and a period of progress of the disease but there is no period of decline. The vital force is not able of curing itself. Under certain circumstances the chronic disease may quieten down and may become virtually devoid of symptoms, but each time it is aroused by adverse conditions and becomes worse than it was during the previous exacerbation.

Chronic miasms are further classified into three categories: psora, syphillis and sycosis to facilitate better choice of remedies.

What would tomorrow's system of treatment and health care be like? It can never allow humans to suffer for the profit of doctors or drug manufacturers; nor it can allow us to live passively unmindful of the questions that shape our existence and unstirred by the need to better our social life. It will have to identify the social, economic and political aspects of the whole termed as health problem; propose concrete ways of solving them and mobilise people to solve these problems. Hence those who are oppressed in such a system of treatment and health care will have to struggle for developing tomorrow's system of treatment and health care. And in this struggle, homoeopathy can became a tool, as it frees us from our dependence on those who are the targets of this struggle.

But before homoeopathy becomes a tool in this great struggle, it must rid itself of all that is unscientific in it, and must not shy away doing so. The most important among them is its secretarianism that the believers and practitioners of homoeopathy so strongly display. One of the reasons for its secretarianism is due to attacks on it and its inability to meet these attacks on the grounds of science. This has been so right from the days of Hahnemann. So vicious has been this attack that even a man of his nature had to limit himself to: "The physician's high and only mission is to restore the sick to health, to cure, as it is termed" (Hahnemann, 1977, p 92). He also added a footnote to it saying, "his mission is not, however, to construct so called systems by interweaving empty speculations and hypotheses concerning the internal essential nature of the vital processes and the mode in which diseases originate in the invisible interior of the organism (whereon so many physicians have hitherto ambitiously wasted their talents and their time)..." But now the times have changed, homoeopathy can meet this attack fully. Besides, history has put a different task before society, especially in poor and exploited countries. If more and more persons are embracing homoeopathy and are even struggling for its transformation, then it only underlines the historical task. And given the social need and the historical task, necessary forces will come forward to help in this great transformation.

Exploding Myths

anant phadke

When the Search Began by Ulhas Jajoo, M G Institute of Medical Sciences, Sevagram, Wardha 442 102; November 1984, pp 50, Rs 5.

MANY health projects especially in the non-government or so-called 'voluntary' sector tend to report exaggerated success stories about what they have achieved, when in reality, things are quite different. Such reports or claims create myths about what health projects can and have achieved. There are a very few exceptions to this myth-making. "When the Search Began" is one such notable exception. It is an unusually frank and critical reporting of the healthwork done in the villages near Wardha by Dr Ulhas Jajoo, his collegues and students from the Mahatma Gandhi Institute of Medical Science, Sevgram, near Wardha, Maharashtra. Instead of continuing the usual arm-chair discussions, this group went into the field, analysed their experiences in a critical and open-minded fashion. They found that many of their initial assumptions, widely prevalent ideas related to healthwork, were wrong. The "search" has been for a socially, economically, politically appropriate strategy for rational healthwork. This story of their search is very useful to any newcomer who honestly wants to do any worthwhile work. It is, however, questionable whether the structure of delivery of healthservices they have formed is radically different from the usual prescriptions (with their blindspots). Secondly healthwork has been equated in effect with delivery of healthservices, with no mention of socio-political aspects of healthwork. Let us understand their work, and their perspective as given in this short report.

Novel Health Insurance

The group decided to go into field-work and describes how, during the rains, their first visit to Punjai, a way-off village, turned out to be so difficult. It frankly admits that they chose a nearer village—Nagapur, because they realised after the first visit to Pujai, that regular work there would be too difficult. In Nagapur, they started with a weekly clinic and a drug-bank with contribution of Rs 4 per family. The drug-bank soon went bankrupt and they realised that this contribution was too meagre to run a drug bank. The initial enthusiasm of the villagers soon waned. The group came to the conclusion that because people were so engrossed in their attempts to somehow get two meals a day, health was not at all a priority, that health-education, immunisation, etc, did not elicit much response since it was not their felt-need. When they touched the villagers' felt-need (e g, getting bank loans) the response was quite different. The report however, does not elaborate how and to what extent the group continued this economic activity. It shifts to a new idea—of collecting grain at the time of harvesting, in proportion to land-holdings. This grain is to act as a kind of collective insurance for free treatment for all acute illnesses for all members of the scheme and also free treatment for acute and emergency cases at Wardha in the Sevagram medical college hospital. The medical college thus supported, subsidised this new insurance scheme in a substantial way. The grain collections had its own problems. The people with larger holding had to contribute more without getting any privileges. They were, therefore, not enthusiastic and half of them dropped out of the scheme after the first year. The drop-out rate was less among other groups. Among landless labourers, the participation increased over years. It is not clear from their account as to why the response to this scheme was better than to the earlier one. No economic or political activity has been reported. Perhaps the support of the medical college including the doctor's monthly visit made the difference.

Honest Reporting

Over a period, the group's activity acquired a certain structure and some credibility. In the course of the work they encountered many dilemmas, learnt some lessons and these have been honestly reported. For example only acute cases could be provided free or subsidised treatment, whereas people expected free treatment for all types of illness once they gave their contribution at harvest time. If a fee is charged for service the poorest, who are the ones most in need, would not get these services. The contributions from villagers could pay only for the payment of the VHWs and their drug-kits, the ANM and the diesel for the vehicle used to transport them to and from Wardha. The author correctly points out that it is a myth to believe that such healthwork can financially become self-sufficient. But the group has insisted right from the beginning that some contribution must come from the villagers. About 35 per cent of the collection from the villagers was kept aside for the payment of VHWs. This was to ensure that VHWs are responsible to the community and not acting merely as an agents of the health-authorities.

The bewildering experiences about their health-educational efforts has been sincerely reported. For example, textbooks had taught them the importance of latrines in controlling diseases. But the villagers had their own problems and hence did not accept the idea of building latrines. They did not have extra money to build even a cheap latrine for each household. Community latrines would be nobody's baby and hence would be left uncared for. The use of sanitary latrines meant fetching additional quantities of water, which was extra burden, mainly borne by the women. The villagers had their own logic for using the road-side (of the approach road to the village) for open-air defacation. It was, they pointed out, the cleanest place during the rains, and was much safer at night due to the street lights! About the small family-norm, the medical team had no counter-argument to the villager's argument that they need two sons so that at least one of them would survive to support them in old age. The medical team realised that unless infant mortality is brought down, old-age security provided, family planning propaganda would not take roots. It is worthwhile to quote their forthright conclusions drawn from their initial experience

(1) Our medical education in the hospital is inadeqate to equip us with the skills required in the rural setting. (2) Socio-economic factors (poverty) and political frame-work of the existing society are major obstacles in the development of appropriate medical care, a field about which we are kept ignorant during our medical education. (3) Medical problems are not the priority need of the people. (4) The awkward-looking behaviour of most of the people is the natural reaction in their environment. Inability to understand their environment is chiefly responsible for the big communication gap between them and we, the educated. (5) In a poor socio-economic setting, idea of self-reliance in health care activities is a myth. The poor community has to depend on someone from outside, may be a voluntary agency or the state. (6) Community participation in health care is more preached than practised. Those who claim it, either do not understand what community participation means or are telling a blatant lie mostly for collecting funds on which they so heavily depend. Collecting people to dole out a gift, which they have never dreamt of, cannot be called community participation (pp 8-9).

Cost Analysis

Their medical insurance scheme however, was a kind of a success. The data that has been quoted (p 14) about two out of the twelve villages in which the work spread, shows that "percentage of coverage for health-insurance" increased from 46.5 per cent in the first year to 71.5 per cent in the 3rd year. (This however does not tally with the earlier claim of collecting contribution from 90 per cent of the villagers in the first year (p 7)). The corresponding figures for labourers and marginal farmers went up from 36 per cent to 78 per cent. In the section "Evaluation and Cost-analysis" they have arrived at a figure of Rs 2 per head per year as the cost of the healthservices (excluding the cost of hospital admission) provided by them. The government of India's per capita public health expenditure of Rs 28 (1981-82) has been quoted to provide a camparison and it has been claimed that "much improved health-services, which have the benefit of involving villagers as contributory participants, can be provided within existing resources, if a new medical strategy is planned and implemented" (p 15). One cannot justifiably draw any such conclusions whatsoever from the cost-analysis of their work. One has to compare the health-facilities provided and the costs incurred and find out whether the costs are less or more. Such a cost-analysis of their work and of the government's work and then comparing them would tell us as to the extent to which the government's work is costly. No such analysis has even been attempted and hence no such conslusions can be drawn from their cost-analysis.

Conventional Barrier

Are there any positive achievements of this work apart from the lessons that the medical team learnt? A collective health insurance scheme (with all its limitations) in rural area, running for five years with increasing participation by the poorer sections of the community is definitely an achievement. Anybody conversant with the field would realise how difficult it is to achieve what appears on paper as small objectives. One may point out that the support from the Kasturba Hospital was quite crucial in the evolution and viability of this scheme.

The achievements in the healthfield are however, quite limited. Using "cluster approach" (collecting, immunising all the eligible children in a cluster, in one day) 95 per cent of eligible children in a few "villages around Sevagram" were immunised. This is a notable achievement. This "cluster approach" is demanding in terms of mobilisation of the people and very few healthprojects have adopted it. Using the same approach, for polio vaccination, in six visits, 81 per cent of the children received three doses and 55 per cent received five doses—this also is by no means a small achievement. Rational selection and use of drugs, preparation of cheaper formulations like a cough-mixture and a few ointments have been reported. But for the rest, a familiar picture emerges—Village Health Workers working for a paltry "honorarium" of fifty rupees per month, a full-time trained Assistant Nurse Midwife supported by a hospital facility nearby. There are many problems in this approach; some of which have been mentioned by this report. The ability of the VHW to diagnose and treat is very limited; much more limited is the likelihood of people having sufficient faith in them about these functions. A monthly visit by doctors is too insufficient; emergencies cannot be dealt with at all; health-education is never taken seriously unless imaginative and special efforts are attempted. A paltry drug kit of a very limited amount (a mere Rs 30 in this case) with the VHW is too inadequate to meet even a fraction of the drug-needs for minor illnesses; unecessary domination of doctors is hardly challenged.

To assess the "morbidity load" (amount and type of illnesses) in the community, and to determine on the basis, the type of health-activities to be conducted, the type and amount of human-power and drugs required, (and not any arbitrary amount) to organise these services through a democratically working team, etc, etc are tasks which have not been satisfactorily resolved. The content and form of health-education which is appropriate and which really makes sense is also something which needs a lot more work . . . there are so many problems and blindspots. This report does not even attempt to throw any light on any of these. Their work has created a learning process. This itself is an important achievement and hence one hopes that this work would not become stagnant, with whatever has been achieved so far, but would take up some of the challenging aspects in the field of delivery of health-care to the people. With all their efforts, the search has only begun and there is a long way to go.

The challenge in healthwork is not only of organising a cost effective, appropriate, rational, democratic mode of health-intervention from the point of view of community medicine. It is at least equally important to expose in practice the socio-political dimension of the established medical practice, to conscientise people about the exploitative, oppressive, mystifying misuse of medical science and to forge an alternative in practice. Such health-conscientisation has to be a part of broader socio-political work. People may not be interested in vaccines to begin with, or in unrealistic health advice. But they do get interested in knowing how the existing medical system exploits them and how to get out of its clutches. If aspects of non-exploitative, liberating healthwork are forged, in practice, such healthwork can contribute a lot. Most health projects have no such perspective of health conscientisation; they are aimed solely at delivering health services. This does not challenge the existing system in a direct manner; Similarly most health projects have no link, have no perspective of forging a link with broader socio-political work.

It is not clear from "When the Search . ." as to how this

work is different from other so-called successful projects in this respect. Most health projects unless they are willing to take large funds from donor agencies, or be supported by big institutions, cannot do any worthwhile work in the field of delivery of health services. (Chattisgarh Mines Shramik Sangh's health work in Rajhara is an exception which hopefully, would duplicate elsewhere.) Health education/conscientisation as a part of broader political work is a low-cost but challenging and important work which has so far not been attempted. This is in contrast to the numerous funded projects in the field of delivery of health care. It must be pointed out that the report under review does not cross this conventional barrier.

A Bird's Eye View of Psychology

Psychology In A Third World Country–The Indian Experience by Durganand Sinha, 1986, Sage Publications.

THE term 'psychology' is a concept borrowed from the West. Thus initial studies were naturally based on Western concepts. This of course does not mean that psychology has not evolved any roots of its own in India. But it is undeniable that Western psychologists and ideas have permeated every aspect of our life and behaviour. Sinha repeatedly brings out this truism in this book covering the psychology scene in India. The purpose of this monograph, done at the instance of UNESCO, was broadly to examine the impact and role of psychology in a Third World country like India.

It is but natural that psychologists in India are very much influenced by the West in the kind of reserach work done. The offspring is bound to imitate its parent till such time that it can form its own ideas and opinions and finally enter its own creative phase. Psychology today in India could be said to have arrived. We are not only able to evolve our own theories and concepts but are also in a position to influence the world at large.

Sinha traces the growth of 'psychology' in India in four phases pre-Independence, post-Independence phase of expansion, phase of problem-oriented research and finally the phase of indigenisation. This can be looked at another way in developmental terms. The infant stage of being shackled to the West; the childhood period where aping went on; the adolescent phase when Indian psychologists tried to break away from the bonds of the West, attempted to coin their own terms and asked questions of their parents and their motives, changed and adapted values and attitudes to suit their environment; and the adult phase where indigenous research is being done and a certain amount of influence being wielded on others, especially in the Third World countries.

The author seems to have taken an unduly critical attitude particularly in his reivew of the post-Independence period—like a harsh parent! Fortunately, as the review proceeds a more objective account is seen.

The bulk of the presentation is in terms of enumerating the research work done in India covering different areas and branches of psychology. But in the area of testing, there do seem to be some gaps. Several tests have been adapted and are apt to our conditions do not figure, e g, Bhatia's tests and child development tests.

Psychology has made quantum jumps in the 60s and 70s but what has not been done is to dispel the wrong notion that psychology means something to do with abnormal people—being the layman's understanding. All the reserach done is commendable, but what has this resulted in terms of follow-up actions and policies? The author himself puts the impact of psychology in these words, "Psychology in India has made significant contributions to the individual and unlimited spheres of our life like in industry, educational and clinical fields because they share many characterstics of similar institutions in western societies where this discipline has developed. But on a macro level and on larger social issues such poverty, inequality, social justice and social change, psychology has yet to make a significant impact." The author's message to practising psychologists and scholars to be 'indigenous' and 'Indian' in their pursuits is very apt for psychology to enlarge its role in our national life.

The book would have added to its stature if the author, with his vast knowledge and experience, had given more emphasis to the future trends and directions that Indian psychology should take—to make it more meaningful and relevant to our society and solving its problems.

The overall merit of the book lies in its broad canvas giving a bird's eye-view of the psychology scene in India. It could be a good reference source for scholars and educationists alike to be aware of what is happening around the country. Its bibliography is in itself a mine of valuable information. Altogether, the book is a commendable effort.

Contradictions Where There Are None

Thomas George

ANANT PHADKE's article "Organising Doctors: Towards What End?" is full of ambiguities and sweeping generalisations. At the very outset Phadke says that doctors belong to a social layer called "the new middle class—a peculiar product of developed capitalist society". One can question the understanding that Indian society is a developed capitalist society; he has given no indication as to how he arrived at this concept. To mechanically transfer concepts developed for Western societies is neither scientific nor helpful.

Phadke has gone on to enumerate four contradictions that doctors in government services face due to what he sees as their 'contradictory class location' betwen the capitalist class and the working class. The first of these is that they are wage earners as well as officers. He feels that since they are officers they will stand apart from their subordinates in wage struggles. It is difficult to understand how this constitutes a contradiction. Is Phadke implying that doctors will seek to crush the wage-demands of the subordinate staff? If so, this is an unreasonable understanding. Wage demands of subordinate staff in no way hurt the doctors, even if they belong to Phadke's "new middle class", since it is not they who pay the wages. So the mere fact that at this stage of social evolution in India the doctors may not *actively* support the wage struggles of their subordinate staff in no way constitutes a contradiction.

The second contradiction that Phadke sees is the one between the need of the government-employed doctor to amass wealth and his limitations as a wage-earner expected to follow the ethics of a noble profession. Here again Phadke seems to have fallen into a widespread misconception. Just because doctors have a relatively secure economic position, one cannot call it wealth. It is true that the government forces doctors to do private practice by deliberately paying low wages. It is also true that very often this private practice is unscientific. But this constitutes a point on which to organise doctors. Most doctors would like to do scientific practice. They would also like to earn a good living. If it can be demonstrated to them that these two things are not fundamentally incompatible, but only appear to be so because of the existing organisation of society, surely they would work to change this organisation. We must understand that the present rulers of India will only provide a level of health care sufficient to keep the people quiet. The quality of health care is not determined by the doctor, it is determined by the government. The government is not interested in spending the amount necessary to provide adequate scientific health care. It will spend only enough to prevent uncontrollable unrest and no more. It will pay the doctors as little as it can thereby forcing them to supplement their income by private practice. The fundamental conflict therefore is not between doctors and the people but between the doctors and the government.

According to Phadke the third contradiction is between the "technocratic scienticism" of doctors (that is, their way of looking at health and disease as primarily a question of interplay of germs and chemicals amenable to drug therapy) and the real need for community medicine. I think that this is vanity pure and simple. Many activists feel that they have discovered the Keys of the Kingdom, the root cause of India's poor health status, and that this is the lack of a "community approach" by doctors. The fact is that every doctor is well aware of the social aspects of disease though he may not have a clear analysis of the Indian social structure, or what to do about it. But is the solution to this problem the "community orientation" of doctors? The government certainly thinks so and the doctors' "lack of community orientation" is favourite excuse for poor health services! But neither the government nor Phadke has cared to explain how doctors are to put into practice this fabled "community orientation" in the *existing* scheme of organisation of society and health care.

Phadke's fourth contradiction escapes me entirely. I don't understand how the fact that "medicine transcends narrow barriers and exposes medicos to universal concepts" and the fact that (according to Phadke) the majority of doctors are from an upper-caste urban background, constitutes a contradiction.

The sad part is that Phadke's analysis leads him to a fundamentally elitist position. He wants to organise only "a small section" for a comprehensive revolutionary change in the medical system because he feels that only a small section will respond to his analysis. History tells us that revolutions are not brought about by small sections of society. So when an analysis leads one to such conclusions, it is a clear indication that one should analyse again and look for and correct the errors in understanding. Only such a scientific process can clarify the debate.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or Marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Primary Health Care, Medical Technology, Agricultural Development and Health, Health in People's Movements.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication which means that the issue on Primary Health Care is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

Politics of Primary Health Care

SINCE the seventies, in many national and international circuits of health bureaucracies, Primary Health Care (PHC) has become a panacea for all the evils of the poorer nations. The WHO has projected it with all its convictions and the member nations have accepted. it with equal vigour. According to the Alma Ata declaration:

> Primary Health Care is essential health care based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self-reliance and self-determination. It forms an integral part both of the country's health system of which it is the central function and main focus, and of the overall social and economic development of the community.

Today when this strategy has been accepted by such a large number of countries, there is a need to examine its potential strengths and weaknesses.

The idea that health is closely related to people's living and working conditions and that it is an outcome of their socio-economic environment was vocalised by men in different fields like John Snow, Engels and later Virchow in the West. It manifested itself in the sanitary movement of the 19th century. In India and other parts of the East it had much deeper roots, visible in the method of ancient medical science itself and in the cultures of Harappa and Mohenjodaro. In India during the struggle for Independence, a demand for comprehensive health care was a part of the national movement. Why then this sudden fervour now for projecting PHC as a new concept by international and national official circles?

To understand the politics of PHC one has to understand the role that UN and WHO have played in the overall politics of the world. Always supporting the interests of the imperialist nations, these organisations have used the liberal tools of aid, support and providing consultancy to diffuse, control and direct crisis situations. The effort to develop an alternative World Economic Order in the 70s was one such spurious exercise and as a part of it, was proposed the notion of alternative health care for the third world.

The motives behind it were to check impending destructive and costly reactions from and within third world nations whose poverty, disease and squalor were becoming threats to stability. PHC was the baby of the liberals in the imperialist camp and WHO projected it as the solution to poor nations' health problems—with full promise of help and support, but a clear understanding that the local political structures alone will give shape to the implementation of Primary Health Care! Such an international strategy which offers free help without any political price is obviously seeking change in health situation with or without the political will of the local government. It is interesting that the international terms of trade are in total contradiction to this attitude. Even though one knows that some liberals have their hearts in the right places, this conflict in international strategy needs serious analysis to understand the reasons for this special concession to health.

At the national level the concept of PHC acquires multiple dimensions. Given the particular hue of the government, the implications have varied from Africa to south east Asia and Eastern Mediterranean regions. The issue is what use does a national government make of the concept? Does it use it as the concept is presented by the Alma Ata declaration and make it a part of its effort to develop an integrated strategy for the betterment of its people, as in Angola, Tanzania and Mozambique or does it allow the concept to degenerate into a slogan behind which the same old strategies with some new features continue to be implemented—at a faster rate perhaps with the additional inputs from the international fund givers—as in India and Pakistan?

A grasp on the national politics of PHC requires an understanding of the country's socio-economic and political structure and the nature of its government and health service structures. Only such an understanding allows one to assess the potentialities or limitations of the system to achieve PHC. An example of the interplay between PHC and politics is the level at which it is integrated into the planning process of a country. Thus, the Chinese and Vietnamese incorporated PHC in the very process of national planning right from the period of their independence without giving it a name. In contrast, India made so much fuss and then relegated PHC to the care of the health ministry while the overall planning processes took its own directions. Yet another example is the implementation and outcome of programmes introduced under the banner of PHC. These programmes which may have a potential of providing much needed services are overtaken by the local power elite through their links with the health and administrative bureaucracies. The nature of the latter thus becomes the primary determinant of the outcome. The Community Health Guides scheme and the drinking water supply through borehole hand pumps in India are two such examples.

Another dimension of the PHC efforts at the national level is the setting of priorities and the selection of technology. In India despite the official acceptance of implementing PHC by 2000 AD, the heavy emphasis on urban-based services and curative approach in rural areas continues with heavy dependence on expensive equipment and drugs. The drug policy needed to provide PHC is yet to be formulated. Can issues of priorities and technology be then isolated from politics? A simple but revealing example is the supply of "electrolyte" packets in the Community Health Guides' kits! Does it not show links between the health administrators and the drug industry who know that addition of so many salts to the basic mixture only increases cost and not effectivity?

If the concept of PHC is getting distorted in the hands of the not-so-democratic government and is becoming a tool for creating two types of services, one for the rich and the other for the poor, should it be criticised, rejected, accepted as an unavoidable distortion or used to broaden the base of democratic movements? These are some of the questions which need to be answered by those who are working in the

interest of people's health. Can PHC as a concept become an inspiration for those involved in people's struggle for their rights? If PHC is an outcome of total development then it should be. And what have people's democratic and left movements done about it?

There are many small or regional projects experimenting with implementation of primary health care. What is the role of such projects in focussing upon the issue of PHC or in diluting it?

In academic circles, in the name of professionalism and the need to achieve results, a concept of "selective PHC" has been circulated which means let us not talk of comprehensive development but do what we can without disturbing the existing balances. This is attractive to those who would like to go back to singing praises to powers of technology and managerial competence. There is need to examine such concepts threadbare to show their reactionary ideology as well as non-feasibility.

Are there any lessons that we can draw from the experiences of the socialist countries which have tried to provide health care not in isolation, but as a part of their total developmental processes? These are the major questions which need to be addressed when one is dealing with the bipronged weapon of Primary Health Care.

This issue examines some of the problems raised in the editorial. Guy Poitevin describes his experiences in taking up health issues as a part of larger movement for socio-economic change. Manisha Gupte comments on the ideology and perspective of the maternal and child health programme and points out that without a questioning of the role of the women in society, any such programme would be ineffective. Asha Vohuman reports on the mass immunisation programme which was launched with such fanfare in Bombay in 1983, not so much because of its potential impact on the health of the children but because the minister in charge needed a visibly successful campaign to consolidate her political gains. The reprinted article from *International Journal of Health Services* provides a historical background of the concept of public health and raises some questions about holistic health alternatives emerging in the US. And in the non-theme section we have Jytte Willadsen discussing the question of the sexist bias in medicine. As a doctor herself she also touches upon the problems encountered in bringing about any changes in the very male oriented medical establishment in Denmark.

We have as usual the Update and Dialogue sections. Sujit Das continues the discussion on the role of doctors; Ulhas Jajoo responds to Anant Phadke's review of his book *When the Search Began (RJH, I: 1)* and *AS* questions if drug therapy in psychiatric problems does not have a place in the present socio-political context.

XIII Annual Meet of MFC

Medico Friend Circle will hold its XIII Annual Meet at Seva Mandir Training Centre, Kaya (near Udaipur), Rajasthan, on 26th and 27th of January 1987.

The theme chosen for discussion this time is *"Family Planning in India: Theoretical Assumptions, Implementation and Alternatives".* Family Planning has generally been considered an important part of Primary Health Care, but over the past two decades, it has come to occupy a key place amongst the country's development strategies. Is its elevation to the level of a panacea, for the problems facing the people, based on well examined theoretical assumptions? What effects has the policy of incentives and coercion had on the performance of other health programmes? Out of the existing contraceptive methods which is the least harmful? Do some of these methods need to be rejected outright? Are there safer alternatives? These are some of the issues to be discussed at the Meet.

As usual there will be no reading of papers. Background papers on related topics will be circulated beforehand to facilitate discussions. They include: (a) Problem of population versus resources (b) Theoretical assumption of FP policy in China (c) Critical examination of the FP policy in the context of the child survival hypothesis (d) Comparative analysis of the dangers of pregnancy and contraception (e) Women as the main targets of FP policy (f) The paradox of higher FP performance in tribal areas (g) Incentives and coercions—effects on Primary Health Care (h) Pattern of resource allocation in our Five Year Plans (i) Evaluation of the existing FP methods (j) Natural Family Planning methods as safer alternatives.

We invite you to attend the Meet and share your views and experiences. We also invite you to write background papers on any other topic to the theme. Your note/paper should reach the Convenor's office by the **31st November.**

Participants are as usual expected to pay for their own travel. Simple boarding and lodging facilities will be available at the venue, on a payment of Rs. 20/- per day per person. We charge a small registration fee to cover the cost of the cyclostyled background papers. Return reservation facilities are also available. If you wish to attend, please write to: **Dhruv Mankad, Convenor, Medico Friend Circle, 1877, Joshi Galli, Nipani-591 237.** We will then send you the venue details and background papers.

Social Dialectics of Primary Health

guy poitevin

This article presents some socio-psychological observations and conclusions drawn from a social study made of a limited voluntary health programme undertaken by a small NGO in remote rural areas of Maharashtra (Sahyadri Range). This qualitative study is concerned with health as a social process. Health practices are examined as components of over-all socio-cultural dynamics and the foundations of a people's health movement sought within the context of a wider attempt of socio-political awakening and people's organisation.

SEVERAL voices raise to draw our attention on primary health issues as components of local socio-cultural dynamics. This perception prevails, for instances, as a conclusion of the assessment of the working of the Rural Health Scheme made by the Population Research Centre of the Institute of Economic Growth: "His (Community Health Volunteer, CHV) role as a public health worker is more social than medical. It would require of him to create health consciousness within the community and to prepare and organise the community effort to carry out all the necessary steps of improving sanitation within the settlement, cleansing up the surrounding areas and imparting health education to all its members. This work within the community is in fact the fundation upon which the whole health care delivery system must rest" (Bose A, 1983: 53-80). P B Desai concludes a general evaluation of the CHV Scheme in India with the following assessment: "The most crucial shortcomings of this kind of approach is the failure to upgrade the capabilities of individuals, families and communities to take upon themselves the responsibility of attaining and maintaining conditions for healthy living within their jurisdictions. In other words, the central issue of the promotion of self-care is left unresolved" (1983: 7). He then stresses the point that the definition of the objectives drawn in the Alma Ata Declaration (1978) to resolve this central issue is 'holistic' in nature, as their formulation insists on a full community participation and a spirit of self-reliance and self-determination (WHO-UNICEF, 1978: 3), and the "task of delivering health care must begin with this non-medical, social endeavour of achieving the necessary social transformation at the grassroot level."

If such is the case, once we have acknowledged and really perceived the social role of the CHV and measured the import of the 'holistic' perspective with which we should approach primary health issues, a corollary immediately follows, that health development schemes should seek the help and the critical insights of social scientists, anthropologists and psychologists. And this is all the more necessary when we are concerned with provision of primary health education and care based on efforts of self-reliance among the most underdeveloped sections of the rural population, whether these efforts be undertaken by government agencies or NGOs. If these efforts are to be "viable, dynamic and positive instruments of social progress" (P B Desai), then primary health schemes should first of all become the subject matter of social science investigation and critical analysis.

We present here below some/socio-psychological observations and conclusions drawn from a social science study of a limited voluntary health programme undertaken by a small NGO in remote rural areas of Maharashtra. The study is not directly concerned with such objectives as the raising of health status, the planning of alternative or integrated health services among deprived rural population and the related welfare, educational or developmental issues, in a more or less static way. Health is examined here as a social process from within a marginalised population, *viz.*, as a dimension of an overall dynamics of socio-cultural and socio-political awakening and people's organisation. The study is concerned with the conditions of a possibility of an effort of health by the people which actually cares for all, based on a critical appraisal by those concerned -i e those deprived of health care facilities—of the present health system and motivated by a will to try out self-reliant ways. This case study is partial contribution towards answering some of the following questions: the need for a strategy for enlisting community participation, the task of generating social health awareness, securing of the cooperation of women more than of men, generating appropriate health practices, organising collective health actions, etc. We may even piously wish or dream that "if we succeed in organising the community for giving to itself-a primary health care system of its own choice, it may become all the more practicable to carry forward this process of self-reliant development into all fields of social and economic progress" (Desai, 1983: 8). But the crucial question remains unanswered beyond the many evaluations of the shortcomings and failures of the CHV Scheme: what does it mean methodologically to "organise the community" for enabling it to wish, to conceive, to experiment, to chalk out and to give itself a health system appropriate to its concrete needs. What does this mean in terms of strategies of social action?

Primary health care as the subject of social science research should therefore be examined and evaluated by focusing on the dialectical relation obtaining between the level of health conciousness and the forms of collective organisation on health issues on the one hand, and on the other, the local socio-cultural, administrative and power structures, including those of the public health care system itself. If health status is rightly considered as an index of social development, health consciousness—as expressed in relevant renewed perceptions and representations and consequent forms of collective action—should be rightly considered as a component and an index of the socio-cultural and politcal awakening of a given population.

The health education and care programme carried out by the voluntary organisation Village Community Development Association (VCDA) in the remote hilly areas of the talukas of Mulshi and Velhe (Sahyadri Range) was considered as providing an adequate field of observation for such a scientific investigation by the Centre for Co-operative Research in Social Sciences, Pune which conducted the study with a grant from the ICSSR. The health programme under study is part

of a wider educational programme (called "School without Walls" and comprising mainly non-conventional programmes of cultural action for children and women directed towards children's and women's organised collective action) which is itself a part of a much wider programme of "conscientisation" and organisation of the deprived sections of the population of several rural talukas around Pune. The health programme is carried out in areas deprived of any medical services. Quite recently, the government made an effort to implement its CHV Scheme. A few private practitioners sometimes visit the area to give injections and to make money from the population. Medical officers of the PHC (Velhe and Paud) do rarely visit the area, except for enlisting "cases" (tubectomy operations). Sanitary conditions are particularly bad. Animals are kept inside the houses. Many villages are cut off by the monsoon rains. In the dry season, very few villages are directly connected by a bus to the taluka centres. The scarcity of land does not permit a sufficient and balanced diet. Traditional representations about diseases and their treatment are generally prevalent.

The main aim of the study was, to document a few possible ways of reciprocal determination, among marginalised rural population deprived of elementary health services, of three series of processes:

(1) The spread of medical knowledge and the consequent improvement of health conditions among marginalised rural population;

(2) The process of socio-cultural and socio-political awakening especially with reference to the representations about health and body and the present disfunctions of the health care system, with the consequent people's collective initiatives of organisational attempts to deal with health problems as well as other related issues;

(3) Autonomous and alternative efforts to promote attitudes and concrete attempts of collective self-help in respect of primary health education and care among the same weaker sections.

The assumption underlying and motivating the study was the conviction of the necessity of such a reciprocal determination: failing this, no health development scheme—be it of a minor scale—can significantly contribute to the radical changes needed in this field. The aim of the qualitative study was to describe and establish the nature, the extent and some forms of this mutual positive correlation.

A second aim was to draw observations and conclusions relating to and bearing upon concepts and procedures of development—and especially of health development— of processes of cultural, social and political awakening and organisation of the marginalised sections of rural population. These latter processes are obviously leading towards redefining the epistemology of development. The case study sheds some light on these theoretical issues with regard to underdeveloped rural masses the health needs of which have been consistently neglected.

Three aspects characterise the methodology: The analysis is jointly and cooperatively carried out at all stages, with those concerned and involved in the scheme, resorting to methods of collective self-analysis and research-action. Such a methodological approach is expected to promote a better critical consciousness and consequently to foster the process of autonomous self-determination as well as develop the theoretical ability of the group of health workers.

The validity of in-depth studies is not to be undermined with regard to the needs of those concerned with macro-planning and large scale policies. Macro-level planning cannot with impunity overlook the conclusions of in-depth analyses. Planning remains a futile exercise whenever it does not take into account the dynamics operating at the grass-root level.

The scheme under study not being a medical care scheme, sampling methods do not suit the objectives of the investigation. The changes occuring in health preceptions, practices and conditions are evaluated by several types of qualitative procedures. One of the most significant is the so-called "sociological intervention": The sociologist and his assistants intervene at the time of seminars and analytical exercises, in-depth interviews of individuals and groups of health workers on a specific theme; personal interviews of villagers; inquiries made by some trained health workers, personnel narratives; minutes and reports of usual meetings and free discussions among the health workers; and role-plays. No questionnaire nor schedules were used; only guide-lines were always carefully prepared for conducting discussions. The study was spread over two and a half years (1983-1986) as a sort of continued analytical effort following and accompanying the evolution of the action programme.

Awareness of Identity among Health Animators (HAs)

The most decisive step consists in generating a basically new approach through a sort of cultural labour prompting the volunteers to discover their identities as HAs in a way quite different from their own expectations obviously modelled after the social patterns and the collective representations shared by the population at large.

After two to three years of health training and practice, HAs unanimously acknowledge their complete unawareness at the beginning of what health might mean. The contrast between the perceptions acquired during many months of continuous training and involvement and the remaining memories of the initial understanding leads to an evaluation of what happened at the begining. First of all, the idea, let alone the wish, of any health activity being undertaken by the population itself, did not emerge of its own from the people concerned or involved as HAs or as beneficiaries. What then was the motivating factor prompting them to undertake health tasks? People from the lower sections volunteered to undertake a health activity on account of the moral authroity that their organisation Garib Dongari Sanghatna (GDS) had acquired and of the trust they had already put on the external social agents who floated the ideal (the main animators acting as catalysts of GDS). It is obvious that without the on-going organisational process such a prompt response, would have been impossible. Without such a collective social support with its components of moral authority and confidence, neither the idea of a health task would have been effectively welcomed by a deprived population nor any man, let alone a woman, from lower sections would have dared to volunteer.

Secondly, in the absence of an awareness of the urgency

of health issues, what representations defined and accompanied the idea of a health task? The possibility of some honorarium was a very strong constituent; the vague desire of some sort of 'employment' was also there; "to become a doctor!" was a widely shared expectation; "to distrubute medicines and pills, to give injections, or to become a dai": such was the most substantial content discretly related to health; some had really no idea of what could be the task expected from them; there was a strong apprehension, especially among illiterate women, about their ability to comprehend; some daring pushed ahead all of them and some liking too. When we compare these initial representations with those brought about after three years of experience, three main shifts appeared to occur in the preceptions. Firstly, from static notions of social status and prestige position associated with the health profession and the expectation of an employment, the approach evolved towards activist attitudes, became action-oriented and conceived in terms of actual achievement. The systemic outlook was altered into a dynamic attitude. Secondly, from self-preceptions in terms of ignorance, fear and inferiority feelings, there was a shift towards self-confidence, boldness. Their ability to assimilate knowledge enhanced the self-image. Inhibition gave way to self-assertion. Thirdly, from an individualistic outlook and wishes of private profit, there was a shift towards a social understanding.

The interest was hence motivated at the start by the hope of a small honorarium (discontinued later on), by the wish to be a 'doctor', by the desire to escape deceptive practices of the private doctors, by the pleasure of getting information "when we realised that we could understand it". The interest of those who had no specific liking for the topic was raised when they learnt something new and delivered a few pills. After two or three years, four main motivations are expressed as follows at the time of health seminars: Let us give information to the people. Let us sit together and educate people. Let us organise the people. Let us be self-reliant. Later new-comers, all women, all illiterate, who joined a scheme which they had observed, give the following reasons for taking up this responsibility: to get a new education and training; if they fall sick, to be able to do something by themselves; the good results of the medicines circulated by the HAs; no money to buy medicines from private doctors, but cheap pills available from the HAs, even on credit; doctors take a lot of money and do not treat unless paid beforehand; interest in this topic; if they now learn, their children can be taught... To the question that such interest may not be sufficiently strong when male pressure is raised against women taking the lead, the answer is that: "We have been selected by a group of people during a meeting. We have the support of people".

As a matter of fact, external support is not sufficient. The female new-comers maintain their involvement out of a strong internal conviction: "We have seen the earlier ones. They committed themselves to this work. They have not eloped or have been taken away by men! The provision of a health education scheme, to succeed or fail for many reasons absolutely alien in nature to the health issues tackled by the scheme. One of them has been suggested above concerning the social factors conditioning the desire for, the access to, the sharing and circulation of medical knowledge among rural lower sections. Secondly, a health scheme is bound in the first instance to be specifically 'recognised' or understood, from a socio-psychologically point of view, through the established patterns of representation concerning doctors, health and therapies. There may be therefore some naivety on the part of action groups to resort to health as an entry point if this means that health, *as such*, on account of its urgency, is expected to easily generate radical social insights. The prevalent unawareness about health as a personal as well as social issue and the deeply imbibed pre-critical and unconscious cognitive structures in this respect make health one of the most deceptive and difficult 'entry points' if one looks forward to it as a lever for radicalising rural populations.

In such circumstances, a main concern of a health scheme consists in defining the role of the HA. This had been and remains one of the main themes of the regular and continuous training programmes of HAs in the VCDA scheme. As a result of discussions among all those concerned by the scheme, doctor, activists and mainly HAs, the following write up was prepared as a basic chart of the HA's role, as an operational model.

Our Health Work: Why and How?

—We and our children fall sick every now and then.
—When we fall sick, we never get medicines soon, nor do we get good medicines.

1. Why do we fall sick so often?

The reasons are that:

1 We do not get enough to eat nor is the food good. Then, as a result, we become weak.

2 We do not get enough of water, nor clean and pure water. As a result in the dry season, scabies increase and in the rainy season, diarrhoeas increase.

3 Our living quarters are small and not clean. We keep our cattle inside our houses.

4 During the rainy season, we work exposed to cold winds and we have not enough clothes to put on.

5 Our work is dangerous, instruments are primitive and insufficient. As a result, accidents occur; we are overworked; we quickly tire and we do not pay attention to our health condtion.

6 Many times, we are overwhelmed by difficulties: as a consequence, our mind does not remain sane. The pressure of the male domination upon women is epecially heavy.

7 The government has no money the government people do not give us information. But it takes great care of a handful of privileged people.

8 Bad habits: alcoholism, tobacco etc.

9 Frequent pregnancies.

10 No vaccination.

If we could get rid of these difficulties, then we would not fall sick so often. But, today, these difficulties cannot be removed. As a consequence, the frequency of diseases cannot immediately come down.

2. Why do we not get proper medicines when we fall sick?

1 There are no doctors in our area; the 'medicine men' are many, they deceive us.

2 The doctors who come into our area, behave like 'medicine men'; for instance, for no reason, they put on a very serious face, use difficult words which they pronounce like mantras and create an atmosphere of mystery. Although there is no need, they give injections and prescribe useless medicines. The medical profession is being converted in to a business like any other business. It is a profession consisting of selling medicines. The more money you give, the better treatment you will receive. A doctor is no different from an agent of a drug company. Doctors behave like dealers: they store the knowledge as shopkeepers

store the commodities and make us more expensive. There is a competition for consumers, (as among dealers) to obtain more consumers and gain more money.
Where is 'humanity'?

3 *What is clear about today's doctors*?

Doctors do just sell treatments. Moreover, on account of the doctors' behaviour, some ideas are firmly embedded in our minds, for example: money is everything; the knowledge of the doctor is very complicated. We shall never be able to understand anything of it; Our health depends upon doctors; Doctors' work is intellectual and of a much higher grade than our labour in the fields.

4 *What is the use of our health work*?

We cannot bring about important changes in our condition, so exposed to diseases with our health activities. The reasons are as follows: Our health condition depends much more on many other factors of our whole environment than on medical factors; the knowledge that we can get about health as health animators is limited. The pills and medicines that we give are simple and not many.
What then is the use of our health work?

We want to bring, at this primary level, a new concrete way of undertaking health work. An example will make it clear. What is the difference in the health work, between the method that is usually followed today, and our method? This will be clearly understood from the following example.

Let us suppose that a lady health animator from our group attends a child suffering from summer diarrhoea, what will she be able to achieve?
Change in the body: We shall be able to win over the disease which affects the body of the child.
Change at the economic level: A good treatment can be given at a very small cost. We can demonstrate it.
At the level of health consciousness: The health animator can change the ideas of the people. What will she/he tell them?

1 Why diarrhoea occurs, what is the treatment, and if it can be prevented. This *techincal* knowledge about diarrhoea will be given.

2 Why diarrhoea occurs much more often among the poor and in the villages. How the proper preventive treatment of diarrhoea depends upon a proper water supply. Why today's doctors and drug companies take pleasure in treating diarrhoea with very expensive medicines. This is *social* knowledge that the health animator is giving.

3 How there is no need for a doctor to treat simple and minor ailments and what is the opposition of the private doctors to this statement.

4 How we can deliver people from the exploitation of private doctors.

5 How in our health work there is no domination of the doctor. We don't give him undue importance.

6 Why, despite so many promises and announcements on the part of the government, this latter cannot seriously undertake genuine health work of that sort.

7 This health work is going on in a nice way, because we are awakened, organised. Our health work will progress to the extent our awakening and our organisation will grow.

8 Still, as long as food, water, shelter, education, cloth, etc. are not available, we shall not stop falling sick time and again.

This definition of the HA's role tries to give a concrete design to a specific concept of health work among and by marginalised rural population. This concept ought to be made explicit. The health work in such a context is conceived as aiming 1) at forging a collective health consciousness based on a critical perception of the relation obtaining between people of lower social strata and their actual physical environment and specific social constraints; 2) at making experimental attempts which constitute *per se* a practical critique of the prevailing methods and structures of the health care system; 3) at projecting in an embryonic form a sort of miniature model revealing the feasibility conditions of alternative values, norms, organisational patterns and practices of medical care; 4) at raising the level of socio-political awareness of the whole population in this respect through health education, self-reliant practices and collective health action as levers, thus contributing, in its own way, to strengthen the overall health movement; 5) at resorting to operational concepts and criteria of evaluation of a social and cultural nature instead of giving priority to and taking only as operative norms the quantitative medical improvements in the health status of a given population, objective that at any rate the NGOs are unable to achieve—particularly the small ones—on a suficiently large scale.

Selection of HAs

A general model remains futile without its operational concepts. The selection of HAs is one of them. With rare exceptions of selection being made by the external main animators of GDS, the HAs of VCDA were regularly selected by local groups of GDS during their meetings (with the 'permission' of the husband or parents for the female HAs). A few women were selected at the start on account of their activity as teachers in a voluntary nursery school of GDS. Sometimes special meetings were called to deal with this issue and several meetings were necessary to make a selection. In the course of time, when new volunteers joined, they were all co-opted by the local groups of GDS. The selection was not a sort of casual appointment but the result of group discussion and exchanges among the assembled people.

When the health workers look back and consider the procedures of their initial selection, they come to the following conclusions.

At the beginning, without any experience of procedures of collective determination, "We had no idea of the method followed, and we did not understand its importance", confess all of them. The cooptation process from within a group for a task to be carried out in the name of a group or mass organisation was a procedure absolutely unknown. They did not realise the meaning of this process. Three years later in 1984, all of them except one woman who dropped out express the firm conviction that it is proper to make the selection from within a group of assembled people taking a common decision.

The reason are the following:

The selection should be made according to the ideas that the people have about it. Their ideas should be taken into consideration; A private selection is a mistake; when there is a decision of a group, the selected person feels responsible to the group and the group responsible to the individual. This is bound to generate a reciprocal questioning of both of them. And such habit should exist; in the case of a private selection, people will not feel like cooperating with the one selected, nor give him/her their support. When a meeting is called, everbody will find an excuse for remaining absent.

The model to be followed in the future is as follows: "In a new village or a hamlet, we shall hold a meeting on health and give some information about it. Then, we should tell the people: "To tackle your problems in this respect you should select your own man/woman for that".

Why should this procedure be followed? This process induces the awareness of a reciprocal responsibility; It avoids the danger of pressures of vested interest and the criticism

or the mockery against the one who is chosen; this process assures cooperation, support and participation; there cannot be any real work by an individual alone.

What do these procedures aim at?

These procedures impart information to the people (doctors never impart information about health and thrive upon the ignorance in which they keep the patients; people get a chance to assemble, exchange and make an effort to solve their own difficulties; the objective is to become self-reliant, "to stand on our own feet"; this helps to strengthen and spread the organisation GDS; the intention is to put an end to the deceptive practices of doctors and of the local miscreants who act hand in hand with the doctors; this brings a health knowledge to the village level; this develops a health consciousness; this gives the women an opportunity of having some role and stand in society; this offers a chance to everybody of speaking out.

Let us draw one clear operational conclusion from these data: the perception of health as a collective issue that confronts the whole community is generated here through a social process of cooperation, by the group, of a volunteer. It is not the perceptions of health as a community problem which comes first and leads to a renewed social practice. It is a renewed social practice which helps developing a new approach towards health, as it could have been with any other issue. There cannot be any real consciousness of collective responsibility unless it takes the form of an appropriate pattern of social relation or a cooperative social formation.

How Villagers Perceive Health Animator

Another determining factor, mainly at the initial stage, is the perception of the beneficiaries and their expectations. Four types of reaction characterise these attitudes, in the perception of HAs, which symbolise four cognitive structures through which villagers spontaneously approach this health experiment.

1 "The village has got a big 'doctorin'!" This derogatory remark related to the women health animators. It points out firstly, that the health worker is considered as a 'doctor'! And secondly, that the prestige and honour implied in this image serve conversely, to ridicule people—, especially the women, or the illiterate workers—volunteering for the scheme being projected so suddenly to such a high position! People did not react mainly in terms of the concrete advantages of the scheme, but with regard to the social image of the doctor and to the concept of health as a doctor's commodity both of them turned into arguments meant to throw discredit upon ignorant people pretending to be more clever than they were to involve themselves in these tasks!

2 This work was looked at as sort of employment for the volunteers. As the possibility of an initial honorarium of Rs 50 was known, the task was considered as resorted to by the volunteers under the motivation of this material incentive. The women would then be able to bring their contribution to the maintainance of their husband and children, as they are the *dhana* of the house, its source of wealth, its *lakshmi*.

3 The third understanding is that this task was just a chance offered to the women's eagerness for being 'set free', abandoning the household duties under the pretext of attending training course in health or undertaking health tasks. Only women upon whom husbands and family could not keep a firm control were so allured. Their volunteering showed their lack of social restraint and fear. "Men and women sit together!" "Women just like to follow their whims!" It was almost out of lust that they had volunteered!

4 The fourth image was that through this scheme, a dispensary would be set up, medicines and pills would be made available. In this respect, as people were saying that "an educated man is needed to give medicines", women had doubts about their ability to prescribe medicines, as they were conscious of their ignorance and absence of education.

These data show that two main and anti-thetic socio-cultural cognitive structures gave readymade referential yardsticks to understand and evaluate the event. The first reference relates to the women's roles and image: a woman should never go outside of the home where she is confined to subordinate and non-prestigious tasks. The second reference relates to the prestigious function and role of a doctor as a supplier of medicines and health services. As the health animators were considered as doctors, these two referential factors clashed and as a consequence, the women were derided, for assuming a role of high rank and superior knowledge!

The basic and spontaneous point of view was not a technical or practical approach, but a social reading; and this reading was no conceptual insight nor analytical apprehension. It was a judgement. The cognitive structures worked, as a judicial recognition, not as an act of cognition. If this is likely to be the case in any transfer, its sucess depends upon the will and the ability to develop a conceptual understanding and to refrain from any hasty and spontaneous interpretation by referring to the in-built structures of recognition which can lead nowhere but to a judgement which is only a reduction to the same. This seals the impossibility of any progress.

This is obvious in our case. If the judicial recognition turns into a judgement against illiterate women and ignorant men taking up the role of a 'doctor', as this is simply a contradiction, still a women may be considered as positively motivated to take up this task for the reason that she wants to bring home some income, for the benefit of her husband and her children, as the source of wealth of the house (*dhana*). This is also a very clear cognitive structure regarding the role of a woman. The understanding of her desire to become a health animator is therefore either, negatively, a will to escape her duties at home and the control of her husband, or positively a justifiable intention of bringing home (to her owner, for the benefit of her house) some wealth, as she is a *lakshmi*.

One operational conclusion can be drawn from this. If a health scheme aims at engineering a process of social change, *viz*, a transformation in the patterns of relationship and values, it should and it could boldly create a situation which will directly challenge the cognitive structures mentioned. For that purpose a health scheme should not start with doctors and medical services run by doctors: health should not firstly be looked at as a technical task. Secondly, the leading role in the implementation of the health activities should be given to those women whose health is the most affected by the present health system. These activities should mainly and

basically consist in imparting elementary health education to women and more technical knowledge should come as a secondary dimension. A health animation activity undertaken by women of the lower social sections, taking the initiative of visiting and educating village population is likely to prove one of the most effective levers of social change in the rural areas, as this practice breaks off strongly built-in cognitive structures which have a definitive repressive role and are very significantly responsible for the perpetuation of a particularly degraded health status among women: the partiarchal patterns of relationship and values, and the undue prestigious status of the (male) doctors as the only ones capable of dealing with health and medicines.

Socio-cultural Pressures Against Health Animation

Between 1981 and 1984, out of an initial group of 30 HAs (14 men, 16 women), 17 dropped out (6 men, 11 women), while 18 new comers volunteered (1 man, 17 women). Those who remained involved had collectively analysed the reasons why so many dropped out—26 answers could be specifically given for the defection of 17 HAs. These answers are classified into 9 categories as follows:

1:3 male and 3 female HAs abandoned as they did not obtain the expected financial profit. The honorarium was considered too meagre; even this was discontinued and substituted by small help given on the basis of the days spent on house visits and meetings held, etc. Motivations were put to the test.

2:5 female HAs left under the social repression obtaining against women's assertiveness.

3:2 men and 1 women left for reasons of economic pressure and poverty.

4:3 men left out of diffidence about their own ability and social inhibition.

5:1 man and 1 woman were frustrated in their expectation of a higher status sought through this activity.

6:3 left on account of personal reprehensible behaviour.

7:2 women left because they could not cope up with the task.

8:1 woman could not bear the clash between the knowledge received and her traditional beliefs.

9:1 woman left out of lack of proper motivation.

These reasons are indicative of the difficulties and of the nature of the psycho-social determination of those who maintain their involvement with a renewed conciousness. It is obvious that almost all HAs joined the scheme with the thought that they would get a sort of paid employment thus improving their low social status. As a matter of fact, if all of them could secure through this programme somehow better social position, a qualified social recognition and some social respect—and self-respect—, paradoxically would remain more involved in the scheme than those who were usually deprived of such social respect, often denied the right to talk in the open and assert themselves, while those who already enjoyed some social prestige left an activity which appeared to them as not enhancing their dominant social position, or even countering it.

One should be fully aware of the basic difficulties which any attempt of popular health movement among underdeveloped rural population has to overcome before becoming a strength. If we are convined that there is no alternative to such a movement for bringing about significant structural changes in the health care system, we ought to be still more aware of the socio-cultural challenges this implies in the first instance. Two testimonies may convey the magnitude of the challenge. The first one is the testimony of a woman HA whose potentialities as organiser are totally repressed by her husband.

> I was conducting a balwadi under the sponsorship of VCDA since one year. On this account, I was, therefore, going from house to house to fetch the children. I found many people sick during the monsoon. Althogh they were suffering from simple ailments they were going to the doctors and taking injections. Doctors were coming from outside and knew how to take advantage of this situation; they collected and lot of money from the population for this. I thought: let us do something about these minor ailments, through health education. Then I volunteered to become a health animator
>
> Private doctors do not give information on about diseases, they just give medicines. They come to our villages only to raise money from the population. I started telling people thus and trying to convince them. Six women came together and, through the Association, we requested Dr. Phadke to come and impart health education. The doctor used to come twice a month in the beginning and gave us information about the children's and women's health. We were getting Rs 50 as honorarium.
>
> In the beginning, women called me names. But, later on, opposition become less. People trusted the information that we were giving them and followed our prescriptions. Similarly, they could observe by themselves how the government doctors functioned.
>
> When I had to go and attend a meeting (training camp) and spend one night outside, my husband would object. "Who will look after our daughter who has reached the age of marriage? The younger children are going to school: who would look after them?"
>
> I have now after three year accepted the job of becaning health worker of the government so that the health education that I received during these years is not wasted. They organise only one meeting per month. When VCDA stopped giving the Rs 50 honorarium for the health work, my husband became completely opposed to my participation in these activities. This is the reason I accepted government work. And I continued this health activity with the same motivations that I got from VCDA training
>
> With the government we do not have the freedom to function as we think right; we have to do the work only in a very particular way. Although I have accepted the work of the government I like to attend the meetings and the camps for women of the VCDA. My experience with the government is very different. People get absolutely no health education from them. Only one thing matters: to distribute pills, and to keep monthly records. This is what the health officers consider good and important health work.
>
> Still, one should be able to study as we were doing which questions the women should think over and take up. For instance, women started a movement for clean drinking water, as a result of that education.

The second testimony is the account of the difficulties faced at the start by the group of HAs from Panshet whose level of deprivation makes difficulties more acute. 1) The first crucial question was a doubt about one's own ability to follow the teaching of the doctor. "We shall not be able to learn and study." We were not educated: "We did not know anything about health, dispensary, medicines..." There was no conviction of one's ability to repeat correctly the lessons of the doctor. None of the HAs had ever previously attended any meeting or expressed himself in a group. "For three months I just kept silent in the meetings!"

"We did not realise that we were human beings, as much as any one else. We did not know anything about government officers... We were only busy with our house, fields

and cattle. Where is the government? How to go and meet them? We did not have any idea about it. We had no idea that we had also rights. HAs were requested to commit themselves to assume a social role when they had hardly a clear consciousness of their own identity of social beings.

No wonder this generates a strong feeling of self-diffidence. "I am afraid that people will not come and attend our meetings, nor listen to us." Still, "I am convinced that going out to attend meetings, I shall learn something. How long should we continue to submit and surrender to the leaders?"

Going alone from house to house to give information about health was seen as a great difficulty by some. Some felt it was easier to impart health education in a meeting, within a group, when people are assembled together, because there can be exchanges and discussions, and those who understand can help others to learn.

There was the reluctance to listen to women: "They cannot even behave themselves in the society and look after themselves! How should they come and teach us! Men teased the female HAs, especially after having had their drink, "We shall, all of us, now, become doctors!" "Why make everyone a doctor also like you!"

The pressure of the authority of elders especially upon women makes these latter still more shy and inhibited to undertake something new and unusual. Men complain against women that they attend meetings and report there about the drunkards of the village and all their stupid and bad behaviour, and first of all about their insults against the HAs. The pressure of the more influential male leaders was and remains a serious difficulty for the women who volunteer or would like to volunteer.

The countter propaganda objected that outsiders had come and trained HAs who immediately listen to them and follow them, falling a prey to them. "We should only look after our fields, eat peacefully our pancakes of millet. Women should just go to the fields or to the forest for their tasks, earn a few rupees for the house; this is better than attending meeting and roaming about, everywhere, doing nothing, whiling the time in useless activities which do not yield any income. What will you get (money) from this work? What will these people give you?" Aren't they already 'social workers' in our village? (leaders who are supposed to care for the welfare of the community). Local leaders do often call women names because they follow people from outside instead of going to work to bring home a few rupees, listening only to them and keeping a submissive attitude towards them.

Another type of counter-propaganda says: "What did you obtain and what did you give us after three years?" The understanding behind the objection is that the organisation should immediately bring in some material improvements to show its credentials, to the population, free of charge and without any effort on their part. The reason motivating the objection is also that the organisation "of the poor of the mountain" is approaching directly the administration and demanding the implementation of the government schemes for the benefits of the needy, independently of the local leaders who have a vested interest in the poor depending upon them.

HAs insist upon the reactions of the local leaders who see in the HAs and in the organisation a direct challenge to their authority. "They are not Dhanagars (in one area, many HAs were from this caste), they are foreigners: they come to collect girls and send them abroad where there is a want of girls. One should not vote for them. If they can get four votes, we can still have ten of them... Listen to the head-men of the village. This is not proper. Our women should not talk with men from outside!" "The HAs get plenty of money: this is the reason why they roam about". "They get medicines free of charge and take money from us!" As expected, the same leaders make capital of caste feelings to object to the fact that HAs of different castes assemble together, and do not listen to the caste elders.

A few drunkards come to disturb the meetings, teasing, shouting, raising their voices with the result that people cannot express freely their difficulties, despite their genuine desire to do so. In the beginning we did not know how to handle these trouble makers".

Dynamics of Self-Assertion

The interviews of the new-comers—all women who happen to join the existing groups of HAs reveal the following processes:

1)Personal acquaintances and a prolonged time of "wait and see" attitude preceded any decision. The example and the concrete testimony of some one else are necessary as a preliminary step.

2) A clear invitation to join was made, not to elicit a purely individual move but a commitment to participate in a collective effort.

3) The initial step were met with laughter, counter-propaganda, lack of appreciation on the part of the population.

4) The decision to join was personal and motivated by a will to achieve something and dedicate oneself to a task whose relevance was understood.

5) This understanding increaseed the strength of the personal motivation and developed progressively a wider and realistic social consciousness.

6) The motivation takes momentum, against objections, out of one's own effective commitment to tasks which are experienced as beneficial. Action generates self-assertion.

7) The group proves to be the best support for the personal efforts and commitment: A small group of like-minded people is the essential structural factor.

8) The elements of general personality development (self assertion, ability to express oneself and talk in front of a group, capability to understand a knowledge considered as difficult, etc,...) work as an encouragement.

9) When money is seen as the main motivating factor, no effective health animation can be sustained. Monetary compensation may not go against a real interest in health and health education, but once such an interest is maintained by monetary incentive only, we cannot expect it to develop into a social concern and commitment for health animation and community organisation on health issues.

Antagonistic Perceptions and Conflicting Practices

HAs wished to co-operate with the government health services rather than compete with them. A voluntary scheme is no substitute to public health sevices. The several attempts made by VCDA to operate jointly with the government services met with only a little success. As our concern here is with the local socio-cultural processes, we shall consider only the psycho-sociological dynamics obtaining between HAs and PHC personnel rather than the possible forms of co-operation. Let us give due attention to the perceptions of HAs concerning the behaviour and the attitudes of the government personnel, as articulated in health seminars by HAs.

1. Government doctors are to be seen at the taluka centre and in the villages only in the specific plaees where commodities and facilities are available. Government doctors will always be seen in the company of a limited, restricted and specific category of people: with the sarpanch, the patil, the teachers, and sometimes the talathi and the kotwal. Their social place is with the leaders, the rich, the notables, "with those who talk". They will behave with them with civility. They will be attentive and considerate with the established notables and leaders. They will be seen in their home places. They will accomodate them immediately when these latter come to meet tham and they will attend to them without delay, and show them small courtseys. The government accordingly behave also as local leaders.

2. The attitudes which motivate their way of talking and their behaviour lead them to make a show of their superiority and importance. Their arrogance is resented by the people; they do not let others talk and express themselves. They speak fast and loudly over the voice of others as to frighten the people. Their manners show that others are not worth attention, being all ignorant people. "They consider the poor as stupid and childish". With the poor, they are, insulting and offending their feelings; they do not give answer if poor people ask questions.

3. A few features characterise their language and ways of addressing the common people. They often use words (some special or English words) that people cannot understand, with the purpose of not being understood. This language shows their superiority and "if we ask, we are left with the following answer: "You are ignorant! What can you understand! Don't you have confidence in me?... I told you once, I shall not repeat... and so on they simply do not care for whether we understand or not: nor why we cannot understand.

A second feature consists in not giving information about any disease: they would just hand over medicines. They never impart nor show any readiness to impart knowledge about health and disease. Mainly concerned with cases of family planning, they do not give due attention to the sick. Expectations regarding money are another main feature of their behaviour. The question may often be raised, from the start. If there is no money, the patient may be sent back or adviced to come later, or another day... Money and injections are two main aspects of the doctors' behaviour.

The doctors would also easily entrench themselves behind the laws and rules of the government. They do not appear as responsible towards the population; they are not answerable to the people.

These frustrations and clashes with regard to the medical practices of the government personnel lead to conclusions already often drawn but naturally stressed by HAs in their analysis.

1) The doctor's services are alien to the needs themselves. "Our main expectations is that the government doctors reach us, the poor, who need them. They don't. They never come to the houses of the rural poor". "We don't know what the word nurse mean. If it a thing to be eaten, or an animal?" "We asked the PHC officer to send us a nurse: he just promises but nobody has ever come". Once, at Sakhari, thanks to the firm insistance of HAs, doctors came and HAs helped them to vaccinate the children. HAs motivated and assembled the people. Then the doctors promised to come to another village, Dudhavan, under the pressure of the HAs. But they never did. The false promises of doctors to the HAs are a permanent matter of tension, diffidence and disgust about the government health care system, and its personnel. Another area of tension is the insistance of the government personnel that HAs should bring to them women for being sterilised. The government CHV are supposed to do it, why should the HAs not give priority to this too? HAs answer:

Chart

We HAs	The Government Health Personnel
— We go and visit the poor at home	— They enter only in the house of important people
— We arrange for few cheap and good medicines being supplied to people	— They give importance to medicines
— We give priority to the people	— They give importance to money
—We educate people	— They just distribute medicines
— We look at the patient and give the appropriate medicine	— They don't give all the medicines required to cure the patient
— We think of the whole environment and situation	— They don't bother for the whole environment
— We select HAs taking into account the ideas of the people	— They make private choices
— We organise people for collecting action on health problem	— They don't try to assemble the people
— We promote health consciousness	- They don't bother about health awareness
— Health is a public issue and a political question	— Health is a private problem to be solved by doctors

"You don't give any protection to our childre. Four live and four die. First come and attend to our children, save them and we shall bring you plenty of cases. Otherwise, why should we undergo operations?"

2) The health system is not directed towards the people. Those HAs who were absorbed in the government scheme: "During the training meeting organised by the government every month, doctors and their CHV pretend that doctors are ready to go anywhere. If HAs protest that they have never seen them, that doctors make promises which they never keep... Government doctors and their CHVs look down upon us, repress us as women who talk too much and had better shut up in front of them! When we asked the doctors: "Why do you take money from people, regularly, although you are paid by the government?", doctors reply angrily: "Why don't you take money yourself also from the people?" Doctors insisted and added, addressing a *dai* "before doing any delivery, you must first ask for money from the people". Doctors advise their CHV: "You had better stay at home. Do not visit houses." We, HAs, tell the people: "Go and see the CHV of the government." People reply: "They do nothing. They do not inform us. They do not come and attend us. They tell us nothing, they just give a pill". We tell people: "It is your right to go and meet them and avail from them their services. It is a government service." People reply: "We prefer to come and see you. No improvement is gained from them. They are of no use". Doctors tell us: "You want conflict... You organise demonstrations... We shall also organise such demonstrations... You cannot even sign your name and you immediately strongly reply and object to what we say!"

3) The selection of CHV serves vested interests. In Panshet area, when the CHV scheme started, HAs insisted that women should also be taken, and not only men, and even illiterate women. Some were appointed but no further co-operation could materialise in other places, despite the readiness of the HAs to help goverment officers in the selection and implementation of the scheme.

Conclusion

Strategies of "Health For All" will prove effective when we succeed in translating them into alternative social practices of "Health by the People". The chart on p 50 is an attempt made by HAs of VCDA, on the basis of their experience, to define antithetically, these alternative health practices required as a foundation of a people's health movement among rural marginalised population.

In view of the magnitude of countervailing forces, there is little likelihood of such alternative health practices gaining *on their own* a significantly large and lasting momentum unless (1) they are locally part and parcel of an appropriate wider peasant movement putting out similar roots, (2) externally backed by and related to, other branches and forces of the national health movement and (3) internally born by a permanent self-learning exercise addressing the anthropological, socio-cultural and ideological dimensions of the primary health issues. For lack of space, we did not deal here with these pedagogical, anthropological and ideological components as essential to any effort towards health by the people.

Immunisation as Populism

A Report

asha vohuman

A mass polio immunisation campaign was launched in Maharashtra in May 1983 with much fanfare. The 'war on polio' was meticulously planned and 6,000 volunteers mobilised, the All India Institute of Physical Medicine and Rehabilitation acting as medical advisers. By the end of July two-thirds of the slum colonies were supposed to have been covered. The article takes a closer look at the campaign and discovers shocking lapses. The campaign it is pointed out, was merely a gimmick created to aid and abet the then health minister's political ambitions.

THE use of health in populist politics is as old as the Emperor Ashoka. But it is difficult to find as blatant an example as the mass Polio Immunisation Campaign launched in May, 1983, by the then health minister of Maharashtra whose "War on Polio" campaign warrants close study for its sheer ambitiousness, and its unabashed use of a health intervention to achieve a tawdry political end.

Before one describes the programme or rather, "campaign", it is vital to understand the motivating factors behind it. The appointment of this particular health minister had been violently opposed even from within her own ruling party ranks. Within weeks of her appointment, there were several moves to oust her for "incompetence" and being for "an embarassment to the cabinet". The Chief Minister apparently warned her that she had to do something to effectively silence her opponents or he would have no choice but to replace her. Evidently, a considerable part of the furore over her appointment was caused by communal factors, since the health minister was a South Indian by birth (though domiciled in Maharashtra for over 30 years) and her Bombay constitutency was also predominantly South India. Yet another source of political pressure on the minister was the falling popularity of her party especially among the poor, who had, in the previous elections, voted largely for Opposition candidates.

Thus it was that the beleaguered health minister had to find a quick means of securing her own position in the Cabinet as well as improve the party image among the City's poor and a means which was within the confines of her portfolio. She hit upon the idea of the "War Against Polio" as the proverbial stone which would kill both birds. We shall see why this was a brilliant choice.

Consider first of all how beautifully polio immunisation in a image compaign fits the bill:

When asked "Why polio?" the health minister reportedly said "other vaccines like triple, the child gets fever. The parents are upset and don't bring the child back for second dose. Also, these reactions would be used by our opponents to spread fear and make the compaign fail. With polio doses, we were confident that this would not happen."

"I had to have a programme which would take my party workers into the slums, doing a good community service, to improve the image of the party among the poor."

"Another thing—anyone could give polio (sic) because it need not be injected. So with polio, I need not depend on medical people to help me. I could use our party people and volunteers".

Several observers of the programme commented on how candid the health minister was, privately, about her political ends. She did not bring in unnecessary rhetoric about which rationale was reserved for public consumption: such as one of the printed "public appeals" which said: "Of all these diseases, polio is the most dreadful... (it) not only causes death but also produces permanent disabilities of varying degrees, which not only makes the life of the children and parents miserable but also burdens...Society. This problem is more acutely felt in the case of female children due to the problem of difficulty in marriages..."

"...There is no specific treatment for this disease, that is why it is extremely important to protect every child by immunisation as early as possible".

Having chosen her medico-political weapon in March 1983, the health minister planned the war with a meticulousness which would do credit to a Field Marshal. It was decided to launch the campaign on May 1, Maharashtra Day, (ironically, Labour day as well) with maximum fanfare. The planners then worked backwards, systematically plotting and preparing each step.

With 30 years' experience as a family physician the minister knew that if the cafeteria approach would work immunisation would have to be taken to the dorrstep of every eligible family. Existing health manpower in the city was not touched overtly because their routine duties should not suffer, but actually because they were unlikely to cooperate and even if they did, it would not ensure that the credit went to the minister's party and party workers.

Thus a broad spectrum of organisations and institutions were approached—colleges and schools (whose students were promised extra marks in return for their participation), "social organisations" (which were by and large communal and caste groups interested in "public service"), clubs like the Lions, Rotary, and Giants, political parties, and associations of the medical fraternity like the IMA. The Directorate of Health Services and the Bombay Municipal Corporation was asked to provide support services in the form of vehicles vaccines and equipment but were otherwise kept on the periphery. The All India Institute of Physical Medicine and Rehabilitation (AIIPMR) acted as medical advisors to the programme. Even the Bombay Restaurant and Hotel Owners' Association was approached to provide cold-storage facilities and ice to immunisation teams to maintain the cold chain at the field level. Within a month, not a single source of help and support was left untapped. By May 1, some 6000 volunteers were standing by.

Meanwhile, the problem of identifying the target areas and members was taken up. In consultation with the AIIPMR, it was decided that the campaign should aim to cover only 0-5 years old living in slums with 3 doses of vaccine. To

determine exactly where and how many, the polio-endemic identified in a survey conducted by the AIIPMR in 1981 were superimposed on ward-wise maps of the city. Teams of student volunteers accompanied by party workers then fanned out into these areas to survey the number of un-immunised under-5's and within weeks delivered the target figure: 1,00,000 children. This enabled the organisers to promptly obtain adequate supplies of the vaccine from the Haffkine Institute.

The campaign plan was now further elaborated and entrustead to a team of 'campaign managers' each with a specific set of responsibilities: e g, manager-volunteers (enlistment, deployment, supervision); manager-vaccines (cold chain maintenance, supply, distribution); manager-publicity (printing, media, etc), manager-transport (commandeering, co-ordination, deployment), etc, etc. Each campaign manager was a trusted party lieutenant of the minister's, personally loyal to her. In addition, a "Ward Chief" (again a trusted party worker) was appointed to co-ordinate and supervise all activities at the ward level.

Publicity came next. By early April, thousands of poster, banners and hand bills were flooding the target areas. Party workers addressed hundreds of local public meetings to spread awareness of the campaign and to enlist more volunteers. But the minister's coup-de-etat was undoubtedly her "padayatra" through the slums accompanied by polio-affected children. In each locality, the crippled child was made to address the people, appealing to them to immunise their children and prevent them suffering a similar fate.

Simultaneously, immunisation cards were printed in thousands to be filled in by the vaccinators and handed over to the parents as a record, to ensure completion of the doses and prevent double immunisation of the same child.

The problem of supplying thousands of flasks to the immunisation teams was solved by asking the volunteers to bring their own flasks. Hotels and restaurants near each target area were alerted a day before to kep supplies of ice ready for the teams. The vials were themselves deployed to there focal points the day before and kept in their deep freesers.

An intelligence system was also set up to achieve an efficient, up-to-the-minute flow of information regarding immunisations performed (area-wise, dose-wise), vaccine supply, member of volunteers and their deployment, and the transport position. The campaign would start on the first Sunday of every month (to enable the maximum member of volunteers to participate) with mop-up operations for each dose on the following Sunday.

This is only the bare bones of the campaign's organisation, since a detailed description would take up a book. But it is clear that little was left to chance of accident—far too much was at stake, politically, for any risks to be taken. One observer records that the team-spirit and hardwork put in by the minister, managers and wardchiefs was most impressive; but also very aggressive, as if daring anyone to criticise or better their efforts.

The "War Against Polio" began on May 1, 1983, with the then Governor of Maharashtra symbolically immunising the first child from a central city slum at 8 am. By 7 pm some 70,000 immunisations had been performed, or 70 per cent of the target figure. The second round was conducted on June 5, with 85,000 doses being administered—60,000 second doses and 25,000 first doses. By end of July, a total of 1,35,000 0-5 years old had received first doses, 50,000 had received two doses, and 85,000 children had received all three doses. Two-thirds of all slum colonies in the city were supposed to have been covered under the campaign. This, of course, is the Gospel according to the health minister's cohorts, and is quite open to interpretation, as we shall see.

Having understood the motivations for the campaign, and the plan of action, we can now take a closer look at what actually happened.

As pointed out earlier, virtually none of the considerable health resources directly under the health minister's command were utilised in the campaign. The role of the state Directors of Health Services, for instance, was limited to ensuring supplies of vaccines and vehicles for transport (though the latter were apparently withdrawn by the Directorate after the first round), printing the publicity material and forms, and "arranging" meetings (though not attending them). One Assistant Director of Health Services is reported to have said: "This is another political tamasha. We are here always; we have to serve the people and face them throughout. These people come and go, so they have to make a tamasha while they are in power". He was also bitter that the Directorate had been ignored entirely because the campaign organisers wanted none of the credit to accrue to anyone else.

Notwithstanding this, a sizeable number of public health service doctors and officers actively participated in the campaign in their personal capacities. They were frankly seeking political favours by associating themselves with the campaign. One municipal health officer apparently absented himself from his normal duties for the duration of the campaign, knowing his superiors could not touch him without risking political retribution.

As for the much-proclaimed involvement of "voluntary organisations", they were conspicuous by their absense. Not a single secular or progressive grassroots agency working in the slums was approached to assist the campaign, despite their initimate knowledge of the local people and their extensive networks. The health minister was dismissive about this, telling an observer "They have done nothing all these years. If they had, we would not have to do this now". An aide was evidently more blunt: "We approached mainly the South India social organisations; we ourselves being South Indian, we felt that they would give a better response. The North Indian organisations we approached did not take much interest. But on the whole, very few of these organisations have done very much... That is why we are relying mostly on our own party workers." In response to why they did not involve grassroots agencies working in slums, the same aide reportedly said, "Why should we ask them? We wanted to show what (our) party could give the people—and have succeeded. Why should someone else take the credit? Can they run the country?" The defence rests.

The poor involvement of medical organisations, particularly IMA members, was interesting. This was apparently because several leading paediatricians advised the health minister not to launch the campaign in May, since epidemiologically this is a peak period for poliomyelitis. Mass immunisation at this time could, in their opinion, actually

increase the incidence of the disease. Other members sheered at the whole campaign as a political tamasha with which they had no wish to associate. The organisers, however, ascribed a different motive to the attitude of the private practitioners: that they couldn't care less about the slum dwellers.

Let us now turn from the medical fraternity to the legion of volunteers (mostly college students) mobilised into vaccination teams. These were the "front-line" of the campaign and therefore vital to this success. It is shocking in the extreme therefore that a campaign in which so much detailed planning and preparation went into every aspect, no one bothered about training the volunteers for their tasks.

On the morning of each of the campaign days, hundreds of student volunteers would be milling around the health minister's residence, without a clue as to why or what they were there for. The majority did not know, until they were actually taken to the sites, that they were to perform immunisations, much less which vaccine was involved. To ask if they were aware of polio, and the concept and importance of the cold chain, was an exercise in futility. One journalist got the following response from scores of students when he asked them if they knew what they were going to do that day: "They said they would explain everything when we reached the place. They haven't told us anything. The college also said these people would tell us what to do".

One eye-witness reported that the entire gamut of information to the volunteers—from maintenance of the cold chain ("Keep the vial in the flask. After you open it keep it in the saucer with ice"), how to measure and administer each dose, what questions to ask the parents, and some contra-indications—was packed into a five-minute lecture at the entrance to the slum, before the teams were give their vials and told to fan out. The claim made by the organisers that each team was accompanied by a doctor, nurse, medical student or student nurse was more fantasy then reality.

Qualified observers who accompanied the teams were horrified at the repeated breaks in the cold chain, and the administration of the vaccine to children with several contra-indications. For example, unopened vials of the vaccine were carried in handbags (not in flasks) for hours together in 38° C temperature (May being the hottest month of the year); opened vials were exposed to sunlight for nearly an hour, with all the ice around it melted away, and then the same vial used to "immunise" more children; infants with coughs, colds, diarrohoeas were immunised; infants were breast-fed within seconds of swallowing the vaccine. This bizarre scenario was compounded by the fact that the same volunteers were rarely present at the next round of the programme. The high turnover of volunteers ensured that each round was as bad as the previous one. No one thought it worthwhile to train these volunteers in even basic procedures to ensure cold-chain maintenance and effective immunisation. But then, this was not really the objective of the exercise.

The real objective of the campaign was well achieved, in the words of one aide: "Our party workers are acompanying every vaccination team to tell the people that this service is coming from the (name of the party). I am confident that in the next election, these sections will vote for our. . .candidate—these slums will be behind our party from now on". One consultant observing the programme confirmed this: "In two slums I visited, I asked whether polio vaccine had been provided by the government. The answer was "No, not by government—by party".

Let us now examine the role played by the medical advisory institution which was assisting the campaign as their technical watchdogs. Far from watching, they followed a "see-hear-speak no evil" policy which destroyed any chance of this politically-motivated campaign achieving some social good. Either the Director of the Institute or a senior associate was present on all the campaign days. But while they admitted their fears about the programme in private, they were far too intimidated by the presence of political power to do so publicity, not even directly to the health minister and her aides. They simply joined the ranks of yes-men surrounding any politician—rendering the Hippocratic oath into a hypocritical one.

What about the people themselves? If reports of the campaign are to be believed, they were far too wise to reject any gratuitous offering, even though few knew what it was. The vast majority of mothers when asked, had no idea that their children had received a vaccine against polio, thinking it was against tuberculosis, measles, smallpox, or tetanus-but none refused. This was simply because in most slums, no one had actually seen a polio-affected child (except in the padayatra) and those who had could not see the connection between the physical disability of a 7 year-old and the pink drops given to the 7-month-old. This is not surprising in view of the fact that the AIIPHR survey itself had found the incidence of poliomyelities to be highest in the lower middle class group and not among slum dwellers. The publicity campaign which the organisers had designed to "create an awareness" was clearly aimed at an awareness of things other than the causes, symptoms, effects and prevention of polio.

As for actual coverage, there was considerable evidence that the elaborate system worked out by the organisers for "initial attack" and "mop-up" phases broke down rapidly under the sheer weight of the tamasha being enacted upon it: entire pockets of "target" slums had not been touched—the teams had covered the peripheries and left; more often, people complained that one round had been completed with the promise to return next month, and the teams were never seen again; in other areas, two rounds had been done before the disappearing act; in some of the poorest areas, cynical parents told a visiting observer "May be them came-may be they didn't. How do we know? Why should we care?".

Consequently, experts who closely monitored the campaign feel that not more than 25 per cent of target children actually received three doses of vaccine, and that under the prevailing conditions, only about half of these were effectively protected against polio.

However high our eyebrows rise, the fact that the health minister retained her place in the cabinet—for the duration of that particular ministry, at any rate—is now history. Heady with the "success" of the "War Against Polio", she quickly abandoned the campaign to her lieutenants to complete as best they could, and moved on to new pastures: *viz*, a "War Against Leprosy". But for the battle-weary poor, one question remains: Will the wars against them ever cease?

Programming Reproduction?
Maternal Health Services

manisha gupte

In the absence of a basic questioning of women's status and role in society, birth control, abortions and even maternal health care end up merely replacing an old set of traditions with new ones. Do maternal and child health services as they exist today have the potential to emancipate or to further bind a woman to her traditional role albeit in subtler ways? The article contends that the entire primary health programme reflects social attitudes towards women, viewing them primarily as mothers or as potential mothers.

IT is no more a disputed fact that working class women participate in production with men and that like the latter are alienated from the means of production. What makes their position still worse is that women participate more actively in reproduction than men do and yet unfortunately the former are alienated from the means of reproduction as well. Juliet Mitchell argues that as in capitalist production the social product is confiscated by capital, so is the child snatched away from a woman (Mitchell, 1966). Not strictly speaking, perhaps so. In patriarchial society, the child, a result of physiological and emotional interaction is seen as property, and male property at that. Concepts of illegitimacy and patriarchial lineage are examples. A child, created so actively by a woman, grows up in a capitalist and sexist milieu, and alienation occurs through the conditioning and values that she or he absorbs since infancy. Physical alienation does not usually occur because both women and children are conditioned socially not to question or to rebel inside the family. When women do so, physical alienation too does occur in the form of custody in divorce, since custody is more often than not in favour of the male.

The changing role of the family further determines the newer roles that a woman performs within and outside the family. The institution of marriage too on the exterior becomes rather destabilised, say for example through a divorce or through voluntary rejection of marriage by a sexually involved couple. However, the psychological and sociological functions and grip of the family remains the same—it creates the 'masculine' and the 'feminine', resulting in a 'man's world' and a 'woman's world'. It also conditions the newly born infant to accept and appreciate the 'security and stability' that the bourgeois family has to offer.

The prescribed role model of the husband-wife-child determines and influences the roles that men and women perform within and outside the family. As a vivid example, one may quote the doctor-nurse-patient relationship being analogous to the earlier mentioned hierarchal familial triangle. Looking deeper, these role models by virtue of their predecided status determine the extent of food, health facilities, education and employment opportunities that men and women will receive in relation to each other. Therefore, even though women do enter the production force with vigour and compulsion, they inevitably land up doing jobs that are qualitatively and thus economically inferior to those performed by men.

The wage system continues to be structured according to the assumption that a woman's wage is only supplementary. Women are thus seen as economic attachments to men, not as free labourers who participate equally (Rowbotham, 1973). Women are thus financially compelled to stay with their men even in the face of unmasked oppression. Separation and consequently living single or with the children and without a man, often means a drastic drop in the standard of living for women, if not abject impoverishment.

With enforced backwardness, it is also easy to push women out of the labour force more easily than it is to push men out, be it due to automation, unemployment or the omnipresent and omnipotent reproductive duties. Women thus become a reserve army which will work at half pay and who will be reabsorbed by the family if there is unemployment (Rowbotham, 1973). Underpaid outdoor work, invisible domestic labour and conjugal duties therefore leave a woman vulnerable to be doubly exploited. Unfortunately, though the condition of working class women is ideal for the creation of a powerful political force, their realisation of exploitation dissipates instead of being sharpened. The shunting from reproduction to production and back to reproduction acts as a safety valve to smoothen conflict.

The changing role of the family also determines the reproductive potential of the woman. The family in turn is governed by historical inevitability, market compulsions and often by the prevailing political will where reproduction is concerned. In peasant households with considerable landholdings it might be desirable to have as many extra pairs of hands as possible; similar may be the case in not so advanced capitalism, where the quantity of workers needs to be maintained at a high level so that their exploitation through underpayment is possible. With the decline of labour-intensive industry and with the emergence of capital-intensive industrialisation however, the main economic task of the family would no longer be to produce a large number of children, since then quality rather than quantity would be important in the labour market (Morton Peggy, quoted in Mitchell, 1966). The family adapts itself accordingly, and in turn monitors the reproductive ability of the woman to suit the requirements of the contemporary wage market.

The woman in question therefore, is only seemingly liberated to become a wage earner. In truth, however she holds no real power in either structure; in fact forces that are alien, incomprehensible and beyond her control monitor her, both inside and outside the family. In the existing context, birth control, abortions or even good maternal health care, in the absence of the basic questioning of a woman's role in society, end up merely replacing an old set of traditions with new ones. Not only does the woman perform the necessary functions that the traditional orthodox set up demands from her, but she also faces the 'consequence' of being the modern, sexually liberated bohemian woman.

It is in the light of this framework that we have to view

the ideology of maternal and child health (MCH) services; whether they do liberate a woman even marginally, say from the risk of maternal and child mortality, whether a healthy pregnancy and childbirth coupled with birth spacing gives her more choice and more control over her body or whether the existing MCH programme in form and in content, ends up merely making her a more healthy and well programmed baby making machine. In short, whether MCH as it exists today has the potential to emancipate or to further bind a woman to her traditional role, albeit in subtler ways, calls for examination.

MCH: Sexist Bias in Planning

In a patriarchial world, it is no great surprise that male hegemony would exist in all aspects of health care—at the policy level, at the implementation stage and throughout the delivery of this care. Women as a group therefore have to receive health care that is designed in their own favour. Effective health care, provided free of cost and which is accessible to all, especially to women during pregnancy, delivery and the post partum period should be considered a fundamental right. We must fight to see that no woman or child is at the risk of dying, especially during those crucial months. But we must also emphasise that mere MCH will not do. Motherhood is only one of the roles that a woman may voluntarily wish to perform during her lifetime. She may accept it or reject it and in spite of opting out of motherhood or marriage she is a full human being. Health services must be available to women irrespective of their childbearing role.

The entire primary health programme reflects social attitudes towards women, viewing them primarily as mothers or as potential mothers; in fact health services for women have been termed as MCH services (ICSSR/ICMR, 1981). The same report notes that there is positive evidence to conclude that the health status of Indian women has declined over the past thirty five years in spite of improved MCH programmes, mainly due to the fact that women are more 'at risk' nutritionally and yet that they utilise health services less than men do. They are of interest to the health services only when they conceive or when they have reached the upper limit of child bearing permitted by the government's family planning (FP) programme.

The infant mortality rates too are highly unflattering (114 per 1000 live births in 1980 as compared to 129 in 1971) and there has been no appreciable improvement in the nutritional level of children, in spite of programmes directed towards them, neither has primary education become universal.

To shift resources towards women as a group, it is necessary for policy makers to be firstly convinced that women contribute greatly towards world production—within the family, in the agricultural sector, in traditional as well as modern sector industries and also in commerce. An estimate of 18-30 per cent of the world's families are solely supported by women, while in many others the woman's financial contribution is a substantial component (Wayne, 1985). Statistics unfortunately miss family and informal sector activities, resulting in this contribution to the overlooked. Within the health care system, factors that contribute towards women's ill health are not considered—their socio-economic status, total workload, the daily and seasonal pattern of activity, access to health care and so on. Neither are problems which affect women more severely, such as malnourishment, anaemia and occupational hazards, or those which affect women specifically, such as abortion or spouse abuse considered (ibid).

MCH activities, in an informal manner, began in India around the turn of the nineteenth century: mostly voluntary efforts ranging from enrolling women students in medical colleges to training of midwives and Lady Health Visitors. The first transition of the official control over voluntary direction in MCH came in 1938. In 1953, following the introduction of training courses for Auxiliary Nurse Midwives (ANMs) and public health nurses, most voluntary health schools closed down (Sethna, 1978).

The Indian government's official MCH package includes the antenatal, perinatal and postnatal care, the Integrated Child Development Scheme (ICDS), the National Programme for Control of Blindness, the Programme for Control of Diarrhoeal diseases and Family Planning.

There exists undoubtedly a role, however limited, that MCH can play in a woman's and child's life, provided it is universally available and is of high quality. However, in the absence of a woman's control over her own reproduction, a culturally and socially conditioned inability within her to be able to vocalise her gynaecological problems to a health worker, especially male, and the latter's reluctance to bridge the communication gap by demystifying pregnancy, make the MCH a watered down programme, reduced to a mechanical distribution of iron-folic acid tablets, a mindless target oriented approach towards immunisations and endless weighing of children to identify the 'at risk' individuals in an already malnourished population.

The lack of control over one's own body is experienced by many women in the clinic approach to pregnancy and childbirth. Most often, questions that bother a woman deeply remain unasked. The concept that pregnant women should swallow tablets or receive injections for their own benefit without any active partcipation from their own end reveals the ambiguity and myth of 'people's participation' so loftily considered the basis of the Family Welfare programme in India. In fact, passivity is a fundamental feature of the relationship between the providers and users of maternity services (Graham and Oakley, 1981).

Growth charting, accepted so enthusiastically by our health care system is yet another instance of mystification. When less than ten percent of under five children in deprived sections are nutritionally normal, expensive growth monitoring is unnecessary. If 50 per cent of underfives in India (amounting to 55 million children) were to be covered through growth monitoring charts, this activity of weighing and charting alone would require 110,000 workers annually and would incur an expenditure of US $ 27.5 millions for salaries, $ 20.0 million for Salter scales (one per 100 underfives) and additional expenditure for repairs, replacements, maintenance, transport and new growth charts (Gopalan and Chatterjee, 1985).

Such luxurious and unnecessary activity in fact detracts from motivational and educational work which is of primary importance in child health and nutrition programmes

(Srilatha, 1984). In a country with limited resources for child care, a social *group* that faces a high risk of nutritional problems needs to be identified and standard intervention is necessary to *all* their members (Nabarro, 1984).

MCH and Population Control

The scope of the already small package of MCH services is further reduced by making it a screen to achieve family planning targets. There is constant talk of 'integration of MCH and FP' and under this euphemistic slogan, a curriculum for undergraduate students of medicine and interns has been prepared by an expert committee. The training programme has already been adopted by three teaching colleges. In one year, three courses were conducted, which nine teams of twentyseven professors attended (GOI, 1985, p 125).

In the minds of policy makers, MCH figures not as an independent programme but as a means to reduce fertility. The Annual Report (1984-85) of the Ministry of Health and Family Welfare (MHFW) states that 'to reach a couple protection rate (CPR) of 60.0 per cent of eligible couples by 2000 AD, it is essential that the younger group of eligible couples be motivated to accept spacing and the small family norm *... Moreover, use of spacing methods ... has a significant impact not only on curbing the population growth, but also on the health of the mother and child*' (p 116).

The Ministry's own assessment states that the crude birth rate (CBR) at the end of 1984 should have been 32.6 per 1000 population, whereas actually it was slightly higher—33.6. Whereas 29.4 per cent of couples were 'protected' by the end of 1984 (sterilisations accounted for 23.7 per cent of these), a CPR of 60.0 per cent is desired by the turn of the century. To give the FP programme a boost, especially in backward areas, partial assistance from DANIDA, ODA(UK), UNFPA, USAID and the World Bank has been received to cover 63 districts in 14 states as 'Area Projects' for intensive development of health and family welfare. 'The objectives are reduction of fertility and reduction of maternal and child mortality' (GOI, 1985, p 150).

The government has introduced the concept of Net Reproduction Rate Unity (NRR-1) in its FW programme ... "after considerable experience in this regard (need to control population growth), the country has set before itself the long term demographic goal of achieving NRR unity by 2000 AD, with a birth rate of 21.0, death rate of 9.0 (life expectancy at birth being 64.0 years) and infant mortality rate less than 60.0. In order to achieve this goal, the National FW programme has been and will be strengthened. It is a voluntary programme ..." (GOI, 1985, p 164).

In the context of these new goals'set by the Indian government, the stranglehold of FP over MCH can be fully understood. In fact, the first UN Advisory Mission, as early as 1966 had gone as far as to insist that ANMs should be 'relieved from other responsibilities such as MCH and nutrition' so as to concentrate efforts on FP. This mission stated that "This recommendation is reinforced by the fear that the (FP) programme may be otherwise used in some states to expand the much needed and neglected maternal and child welfare services" (UN Advisory Mission, 1966).

The first double-edged tool within the FP programme came in the form of the Medical Termination of Pregnancies (MTP) Act in the early seventies. Regarded by feminists as a much-desired means to control one's fertility, the legalisation of abortions is in itself welcome. However, the government's interest in this legalisation becomes clear when one notes that by the end of March 1984, in all 4,553 institutions were rendering MTP services as compared to 4,170 at the end of March 1983. In Bombay city alone, 50,000 MTPs are registered annually (Karkal, 1984).

The official acceptance of NRR-1 by the government is especially sinister because in lay person's terms it spells that only one daughter should replace her mother. Thus female foeticide through sex determination (amniocentesis, chorionic villi biopsy) or through sex pre-selection (Ericsson, Japanese method) is inbuilt within the government's population control (PC) policy.

The government's emphasis on 'child survival' rings another ominous bell. Welcome in itself, the slogan is reduced to 'spacing methods'. The earlier mentioned Report of the MHFW states that "since child survival is amongst the foremost factors which induce the couple to adopt the two child norm, MCH programme has been given due importance." The strategy becomes clearer when along with the slogan of 'child survival', the government has markedly increased its budget for FP in the Seventh Five Year Plan period and the emphasis will now be on spacing methods for women. It is estimated that by 1990, spacing methods will account for 20.0 per cent of 'protected' couples against the present level of 5.5 per cent. A Contraceptive Marketing Organisation has been registered to promote spacing methods (GOI, 1985; p. 107).

The government now admits that one-third of all IUCDs ever inserted are removed and one fifth are expelled. The officially accepted dropout rate for IUCDs therefore is 53.3 per cent (GOI, 1986). Naturally, the proponents of population control would be desperate to design a centralised and foolproof system that leaves little or no control in the women's hands to withdraw the contraceptive and it is in this context that the importance of injectable contraceptives (ICs) or implants should be understood. Though ICs as yet do not form a part of the FP programme, a Programme-introductory Study on ICs (Net-En) at PHCs attached to 15 medical colleges is underway. Based on the results of this pilot project it is hoped to introduce this spacing method soon. In fact, according to official plans it was to be introduced in 1984-85. The ICMR is also conducting its studies with Norplant—an implant for women. An appropriate version of this contraceptive was to be available by the end of 1985 to start the programme introduction studies at the PHCs (GOI, 1985; p.107).

It has been decided to intitiate a two million corps of women trained to motivate for FP. These corps will be nonpaid and interestingly, acceptors of FP methods themselves. Another significant move by the government in the near future is to disband all male community health volunteers. Through the IUCD programme, it has been learnt that male motivators cannot do the job where spacing methods are concerned. Male health workers have experienced embarrassing consequences while having to explain Copper-T insertions to a woman or to her husband. To close all loopholes therefore women motivators exclusively would approach women targets henceforth.

Motivation: Distortion of Human Relationships

The state's emphasis on women targets and women motivators is a cause of feminist concern for the distortion of human relations which the coercive, target-oriented campaign brings along. When motivators are women, be they the health staff or primary school teachers, they are constantly threatened with dire consequence such as job transfers, sexual harassment, humiliation and delayed salaries it they fail to fulfil their targets. The dangerous limits are reached when these women are the major or only source of livelihood for their families, when they are single, living in an alien village and are unable to complete targets. Recently, in March 1986, Manda Padwal, a female health functionary (an ANM) in Talasari PHC of Thane district committed suicide after reprimand and order from the doctor in charge to sterilise twenty tribals (Barse, 1986).

These women, with the proverbial sword hanging over their heads, are forced to see every other woman in the village as a potential target. All their conservation, whether at the doorstep or at the village well, invariably ends with motivation for FP. Little surprising therefore that the village women resent these motivators and consider them as scheming nags. The entire fabric of woman-to-woman relationships is eroded in this situation, with each party outsmarting the other whenever possible and harbouring deep rooted resentment mutually.

This distortion of basic human relations and support systems has dangerous political consequences. Sexist bias, international conspiracy and the government's population control policy are responsible for the inhuman family planning campaign. Targets are planned outside the micro-environment in which the masses live. Dangerous contraceptives are dumped by ruthless, profit-hungry multinationals. Yet, all of these are invisible to the rural working class. The only visible oppressor they see is a poor ANM like Manda Padwal; most often the latter being from their own class and a victim of the present system as well. Therefore, the anger directed towards another helpless victim helps the ruling class through a divide and rule strategy. Not only does it break working class solidarity, but it also diverts the issues, allowing the real enemy to escape without confrontation. It makes the rulers seem like paternal and benevolent Caliphs out of the Arabian Nights.

As regards the delivery of health services, the 'integration' of FP with primary health care has in fact had an adverse effect on the utilisation of health care at PHCs. A substantial majority of the rural population utilises the private practitioner in times of illness and the major reason for non-utilisation of government services is the absurd emphasis of the latter on family planning. Women still prefer to be delivered at home by traditional dais or relatives, one reason being that any perinatal or postpartum contact with a woman is immediately seized for target completion in a PHC. Immunisation camps suffer because covertly many such camps are used to gather young mothers for Copper—T insertions.

The overshadow of the population control programme over all other essential public health services is resented by people and results in poor utilisation of all these basic services. It is angering that public health services, especially maternal and child services are used as a bait to lure people towards reducing population growth, without any consideration for the existing socio-economic conditions, the helplessness and the inability of the oppressed sections to rebel. In fact coercion thrives on these very conditions, and it is only a conscious, organised working class that can focus on contradictions, unearth the intricate conspiracies and then demand that the health services be geared in their own favour.

The conspiracy of the ruling class and the inhuman strategies employed by them, often in sugar-coated pills such as maternal and child health or as emancipation through birth control, works to control the lives of already exploited populations. Patriarchy, which has the art of adapting itself to new situations, in fact of moulding new situations to suit its end, prevails in policy making research, medicine and science. Our own demands, be they of safe deliveries, of our children's survival and their well being, or birth control, of abortions and the like are snatched away from us and given back to us blunted and decolourised.

Under the guise of giving us the choice, we are made spectators of our own oppression, be it through dangerous contraception, female foeticide, sex selection, surrogate motherhood or the perpetual tight rope walk where our productive and reproductive duties are concerned. It is therefore, necessary to constantly expose this design and to build a strong women's movement that attacks both class and patriarchial control over the various institutions that govern our lives. We have to relate the personal to the political and should constantly question our role as women within and outside the family.

The Holistic Alternative to Scientific Medicine
History and Analysis

howard s berliner and j warren salmon

The resurgence of the holistic health movement in the US in the 1970s can in part be attributed to increasing consumer dissatisfaction with the present system of medical care delivery. This article traces the rise and decline of modern medicine and the concept of public health by analysing the assumption of hegemony by scientific medicine and its practitioners. Then it describes the challenges that holistic medicine's theories and therapies currently pose to scientific medicine's organisational form and practical content. Holistic medicine is assessed in terms of its organisational and conceptual basis, and the relationship between holistic medicine and the needs of advanced capitalist society is discussed. The article is reprinted in a slightly edited form from the International Journal of Health Services, *10: 1, 1980.*

IN an era of concern over the costs of medical care and disarray in the health-care delivery system, the rise of a countertendency centering on a quest for health deserves attention. A resurgence in the healing arts, manifested through a diverse collection of "holistic health practices," is underway in the United States and Western Europe (1). Movements and theories such as humanistic medicine, transpersonal psychology, parapsychology, folk medicine, herbalism, nutritional therapies, homeopathy, yoga, massage, mediation, and the martial arts have spread widely over the last five years (see for example, reference 2-6). (See also reference 7 and 8).

To grasp the complexity of the emergence of this movement as a social phenomenon today, it is necessary to explore the historical and theoretical dimensions of both the holistic tradition itself as well as the tradition to which it is now in opposition. We begin by describing how the rise of scientific medicine in the late 19th century led to the demise of a prior holistic understanding of health and medicine. Next, we relate the re-emergence of holistic health thought to the broader economic crisis that currently confronts technologically based forms of medicine, as well as to the inability of Western medicine to adequately address the health problems of advanced societies (see refs 9, 10, 11).

Medical Theories and the Rise of Capitalism

In early to mid-19th century Europe, two different theories arose to explain the nature of origin of disease. The first, known as contagionism, postulated that some disease were contagious, spreading via commerce and population migration. the strategic consequence was the quarantine, and the system of quarantine enforcement was intended to shut down commerce and trade to keep disease away from non-infected areas. The second theory, known as anticontagionism, postulated that disease instead resulted from local sources and arouse out of "miasmas" —clouds of rotting matter and filth activated by certain meteorological conditions. The practical outcome of this story was to leave ports and commerce alone, and to eliminate filth and swamps in the disease-laden areas. What makes these previous medical theories of more than marginal interest is their direct association with distinct political perspectives. As Ackerknecht point out (12):

> Contagionism was not a mere theoretical or even medical problem. Contagionism had found its material expression in the quarantines and their bureaucracy, and the whole discussion was thus never a discussion on contagion alone, but always on contagion and quarantines. Quarantines meant, to the rapidly growing class of merchants and industrialists, a source of losses, a limitation to expansion, a weapon of bureaucratic control that it was no longer willing to tolerate, and this class was quite naturally with its press and deputies, its material, moral, and political resources behind those who showed that the scientific foundations of quarantine were naught, and who anyhow were usually sons of this class. Contagionism would, through its associations with the old bureaucratic powers, be suspect to all liberals, trying to reduce state interference to a minimum. Anticontagionists were thus not simply scientists, they were reformers, fighting for the freedom of the individual and commerce against the shackles of despotism and reaction.

The high point of anticontagionism occured just before the political revolutions of 1848. It lost its strength in the wake of the subsequent reaction, while contagionism remained dominant untill its reformation into germ theory in the 1870s.

The leaders of the contagionist movement, primarily high-ranking royal military or naval physicians, were politically unified. The anticontagionists were split between liberals and radicals. Opposing quarantine and state bureaucracy, the liberals favoured sanitary reform by cleaning up filth, purifying drining water, and controlling refuse disposal as solutions to disease eradication. This position attributed disease to a primarily biological condition: the miasma. The radicals instead saw disease (and the miasma) as arising from broader social conditions: the poverty, filth, malnutrition, and oppression bred by nascent capitalism. The liberal position, typified in Britain by Edwin Chadwick's report of 1842, recommended environmental and sanitary reforms that left untouched the production system and its social relations (13-15). On the other hand, the radical position, as typified by Friedrich Engels's *The Condition of the Working Class in England in 1844* (16), fully implicated the developing capitalist system and its class relations for disease, as well as for the class-related incidence and distribution of morbidity (17).

In France and Germany, radical anticontagionists formulated "social medicine", the core of which maintained that resistance to disease was not purely biological but depended on class and social position (18, 19). This orientation implied that the human body could resist or become more susceptible to disease, and that prevention of disease was possible through adjustments or change in the social structure. Thus, in reporting on a typhus epidemic in 1948, Rudolf Virchow, a social medicine physican (and founder of pathology in his later years), called for measures such as free public education, separation of church and state, higher wages, progressive taxation, cultural autonomy for national minorities, agricultural collectives, and full employment (20). With the defeat of the

revolutions of 1848 in Europe, social medicine was virtually obliterated. As the anticontagionists lost power and prestige, contagionism was revived as the leading medical theory.

Nevertheless, anticontagionism had lefts its mark, and the movement of sanitary reform went forward from England to other European countries and America. Between the late 1840s and the 1880s, centralised water supplies, sewage systems, ventilated housing, and improvements in factory construction were all introduced (21). Health standards began to improve. Better transportation between town and country enabled larger quantities of fresh food to reach people. Improved standards of living resulted from successful efforts to gain higher wages and from the general deflation in Europe due to lower production costs (22). Death rates began to plummet. Not ony did sanitary reform improve health status, but it had secondary benefits for capital as well. Centralised water supplies, for instance, removed locational dependence upon rivers, fostering industrialisation. Moreover, water supplies allowed for the design of effective fire-fighting techniques that could reduce the unplanned destruction of capital and lower fire insurance costs. The sanitary movement also assisted in the creation of new industries such as refuse disposal; by the end of the 19th century, trash had become private property—and was collected only when one paid (23). That sanitary reform was controlled by the bourgeoisie meant that it emphasised benefits to capital more than to other social groups. Although far removed from revolutionary class struggles, it was nonetheless progressive.

While the sanitary revolution, as it is called, was proceeding, medical theory was being greatly influenced by technical developments which allowed the visualisation of bacteria. The germ theory of disease emerged in France and Germany during the 1870s and 1880s and became the means for constructing new conceptions of disease and health—conceptions that are still maintained with slight alterations today under the rubric of "scientific medicine."(22)

Germ theory and the theory of specific etiology (single cause of disease) served as the basis for a total transformation of medicine. When germ theory produced its first practical success (vaccines for cholera, rabies, diphtheria, anthrax), popular acclaim mounted. As these discoveries were being made, death rates throughout Europe were falling dramatically, to an extent that was publicly noticeable. Yet, ironically, this decline in death rates was erroneously attributed to germ theory advances, rather than to the sanitary reforms and higher living standards that had actually caused the decline. Studies of death rates for virtually all infectious diseases show them declining precipitously after the introduction of sanitary measures, and well before specific therapeutic interventions occurred (25). Nevertheless, scientific medicine took the credit. The end result was the reification of germ theory, which came to be employed as a total expansion, rather than as a theory that could explain *some* things—but not everything—about disease. Environmental and social factors were no longer considered very relevant to the understanding or causation of disease.

Implications of the Imposition of Germ Theory

Gem theory and the concept of specific etiology were tremendously progressive steps for the development of medicine. Although scientists at the time exaggerated the importance of specific etiology and neglected much previous knowledge about infectious diseases, the importance of these advances cannot be doubted. Germ theory was deeply influenced by the social context in which it developed. The growing strength of the labour movement in Europe, as well as in America, had helped to focus attention on health hazards in the workplace, but germ theory's placement of blame for most sickness and disease on microorganisms served to exculpate industry for responsibility. Scientific medicine, as opposed to the social medicine of the 1840s tended to focus on the biological problems of the individual in order to understand and treat most diseases. The diagnosis of illness was made on an individual basis and treatment or therapy was also individually prescribed.

There are serious problems with this approach, which still dominates contemporary medicine. The physician deals with an individual patient (already a socially determined process) (27). The patient is not an abstract being, but of a certain age, sex, race, and clsss, and has internalised a specific historical experience from childhood to adulthood (28, 29). The taking of a purely medical history individuates the patient; however the disease or injury from which the patient is suffering is received as part of a collective experience in a particular historical, cultural, and social setting. These latter circumstances are as much a part of the cause, and *should be* part of the treatment, as are purely medical facts. (The medical facts themselves are social-historical facts.) Thus the essence of scientific medicine's treatment of disease discourages a proper understanding of disease by excluding from consideration the most relevant internalisation of the external world by the patient. As Wartofsky (30) puts it: "Human ontology cannot be reduced to an asocial or ahistorical biology without doing violence to the very specificity of human biological structure and function itself."

By abstracting disease from its social framework and reducing it to the biological sphere, social conditions could be and were ignored. Scientific medicine became consistent with, and indeed legitimated, capitalist development by integrating a model of healing with the social structure; in so doing, scientific medicine has obscured the relationship between disease and the form of social development. Today heart disease, cancer, and auto accidents are posited as "diseases of civilisation."(31). They are conceived of as necessary consequence of economic growth and industrialism, when it is uncertain that this is so (32).

The greatest decline in the death rate has come from the reduction in infant mortality, attributable mostly to public health measures and not to medical advances. Life expectancy has increased in the United States only when the reduction of infant mortality is included in the statistics—in other words, a man of 60 in 1900 had virtually the same remaining life expectancy as a man of 60 today (33). Despite the fact the expenditures for medical care now constitute almost 10 per cent of the Gross National Product in the United States and are growing at a rate almost twice that of the rest of the economy, it is not at all clear that *health* is improving. Medicine is largely ineffective against the leading causes of death for those under 45 (accident, suicide, and homicide) as well as those over 45 (heart disease, cancer, and stroke) not so much because the biological origin (if any) of these problems is misunderstood as that their social aspects have

been relatively unexplored and unincorprated into medical practice.

Success in finding specific causative agents for infectious diseases led to a particular understanding of causation: the view that a specific biological agent was responsible for a specific disease. This assumption remains at the heart of modern epidemiology, even for the study of chronic diseases.

Epidemiological research, especially after World War II in the United States and Europe, has attempted to link social and economic factors to morbidity and mortality distribution. Social epidemiology, as this type of reserach is called, received emphasis during the War on Poverty programmes of the early 1960s and, at the same time, gave some scientific justification for their inauguration and continuance (34, 35). Studies indicated differences in occurrence, severity, and length of specific illnesses based upon a person's income, race, age, and especially class. While these findings become widely accepted within the discipline of epidemiology, they never had a substantial impact on medical education. (In fact, most health workers, including physicans, are not taught epidemiology.). Yet, just *associating* a relationship between social characterstics, disease incidence, and health status does not fully explain the totality of that relationship. To the extent that social epidemiology was content to remain on a descriptive level, it became merely a form of demography (36). While social epidemiology allows for the use of "multifactorial" explanations for disease occurrence, it still tends to rely upon a notion of specific etiology and sees social and economic factors as contributive rather than causative.

The search for a specific cause tends to preclude a thorough and exact analysis of the particular societal context. This problem can be illustrated by the relation between smoking and lung cancer. While smoking is clearly *related* to lung cancer and people who smoke are far more susceptible, there is no *known* agent transmitted from the cigarette into the lungs which can be said to specifically cause the disease. It cannot be maintained by remaining within acceptable grounds of epidemiological thought that cigarette smoking *causes* cancer, although a high correlation between smoking and lung cancer incidence exists. In other words, where causality is multiple and/or approximate, no firm conclusions can be drawn that are generally acceptable within the scientific community.

If this is true of cigarette smoking, where the effects are relatively apparent, image the difficulty in trying to establish the causative nature of industrial pollutants, occupational chemicals, or excessive noise-all of which clearly fall outside the notion of cause that is accepted by classical epidemiology. Consider the difficulty in firmly establishing the causative nature of specific social, economic or political factors, given these limitations! The methodological emphasis on determining a direct causative link limits the study of many of the more pressing problems of illness in advanced Western society by its reductionist orientation. Moreover, research scientists, as opposed to epidemiologists, often try *not* to think in terms of multiple causation. The following quote (cited in reference 37, p 29) from Lewis Thomas, M.D., president of the Memorial Sloan-Kettering Cancer Center in New York, is indicative:

> It has become something of a popular notion to say that the diseases we are left with, now that we have got rid of the major infections, are in some sense so complicated and so multifactorial, as the term goes, that they have something to do with the stress and pace of modern living—that we can't do anything about them until society itself is remade... I simply can't take that point of view very seriously—not as long as we are as ignorant about the mechanisms of those diseases as we are. We really don't know anything at a dog's level about the mechanism of heart disease, or cancer, or stroke, or rheumatoid arthritis. We can make up stories about them and it could be, I suppose, that they do have multiple causes, and are due to things we can't control in the environment. If that's true—if that should turn out to be true—that would be quite a piece of news. Because it has never happened before. Every disease that we do not know about, and for which we have really settled the issue, so that we can either turn it off, switch if off or prevent it once and for all—every such disease turns out to be a disease in which there is one central mechanism. ...In the case of pneumonia, it's the pneumonococcus, and in the case of tuberculosis, it's the tubercule bacillus, and in pellegra, it's a single vitamin deficiency, and I have a hanch, of course, I can't prove it, that it will turn out to be that way for cancer.

For all the billions that have gone into cancer research, no single etiological agent has been found. But the WHO claims that 80-90 per cent of all cancer is environmental or occupational in origin, hence preventable in some way (38). Although there are constant pronouncemnts on the cause of heart disease (e.g. highfat diet, excessive sodium intake), none appears to be specifically responsible. The most fruitful approach to the control of heart disease may be the alteration of the social environment (i.e. stress reduction) (39). Suicide and homicide are obviously not amenable to biological answers, despite the protestations of the sociobiologists (40).

Therefore, the present understanding of medicine and disease spread is most valuable for infectious diseases—ones that have largely been brought under control in the advanced capitalist world. For diseases that are not infectious, there does not seem to be specific etiology, or a single cure; it is these diseases that constitute most of the morbidity and mortality in the United States.

Popular Disaffection with Scientific Medicine

It is through the study of chronic diseases, the so-called diseases of civilisation, that one confronts the ineffectiveness of scientific medicine. It was not until the discovery of sulpha drugs and antibiotics in the 1930s and 1940s that modern medicine could intervene in the disease process in a specific way with a relatively guaranteed result (excluding surgery, of course). However, this seeming success with infectious disease both increased the expectation of medicine's capabilities and, at the same time, wreaked havoc with the demographic profile of the Western world by increasing longevity. Thus, millions of cases of chronic degenerative disease resulted in people who would not previously have lived past childhood.

Since the 1960s, a growing disaffection regarding medicine has been noticeable. There are several compounding facets to this: (a) doubts regarding the value of a medicine which prolongs life to old age, but often in hospital or nursing home settings and in a manner which tends to deprive people of their human dignity; (b) ethical questions arising from the inequitable access to and allocation of extremely scarce medical resources, e g, artifical organs, dialysis machines, and certain surgical procedures; (c) an awareness that modern medicine has been unable to cure and reduce the number of cases of certain diseases, despite the large sums of money

spent on research; (d) the realisation that much disease results directly from the degradation of the physical environment, the workplace, and the individual, coupled with a sense that medicine does not adequately address prevention on either the social or the individual level; and (e) the explosion in the costs of the provision of medical care to individuals, the government, and employers. This section will expand on these points and relate them to an explanation of the rise of holistic medicine in the 1970s.

While there has been relatively little change in life expectancy rates for those already over 50 in the United State since the turn of the century, there has been a significant increase in the number of people, and the percentage of the population, living to an older age. In 1900 there were only 3.1 million people 65 years and older, but by 1975 there were 22.4 million, with a population projection of 3.18 million aged by the year 2000—perhaps a conservative estimate (33). This will create a pool of largely unemployed elderly, dependent on a social security system warcked with financial dliemmas and a private pension system unable to maintain parity with inflation. Needless to say, the economic plight of the elderly adversely affects their health stauts. Given that the elderly consume more health resources than other segments of the population, this demographic change implies greatly expanded medical care costs. Currently, 68 per cent of the care for the aged is financed by public monies through legislatively guaranteed benefit packages (41). Medicare has continually had the most inflationary outlays due to current hospital behaviour and failings in the largely proprietary nursing home industry. It is not difficult to grasp why the issue of passive and active euthanasis is now under discussion and why a concern over dignity in dying (and even a life after death) is being promoted in this decade (42, 43).

A somewhat related problem stems from the ethics of allocating scarce medical resources in a demoractic society. As sophisticated medical technology becomes evermore expensive, the question of how to decide who should have access to that technology and on what basis allocative decisions should be made pose a series of critical bioethical issues. A whole set of dilemmas have arisen to further complicate this problem. For example, in the United States today all people with kidney disease can get their treatment reimbursed through the end-stage and renal dialysis programme of Medicare, yet poor women have been denied access to legal abortions through Medicaid.

A third facet of the growing dissatisfaction with medicine comes from the ineffectiveness of medical research in adequately answering the most pressing disease problems today. Results of a curative nature from cancer and heart disease research have been negligible, let alone significant in alleviating these problems. While there have been advances on an individual clinical level (44), the morbidity-mortality data demonstrate how limited these have been. In the face of a population apparently not getting healthier, palliative therapies abound for a wide gamut of current disease conditions. For example, the huge consumption of psychoactive drugs in the United States has been given wide attention. One can only speculate on the numbers of people who use some form of medication or drug (e.g. alcohol) to get them through the day (45).

Another facet of the overall problem results from the mounting evidence that much disease, especially heart disease and cancer, results from the degradation of the physical and social environment. Air and water pollution, radiation exposure, and additives to food substances have all been implicated in the disease process and clearly must be addressed if social prevention strategies are desired. Further, occupational stress and health hazards in the workplace reveal additional social origins of disease (38, 46-49). Millions of workers have been exposed to chemicals whose long-term effects on health were previously considered inconsequential (or in some case known to be hazardous but used anyway). Greatly increased cancer death rates among certain categories of workers will emerge over the next two decades. Moreover, the degradation of the individual citizen through lack of exercise, inadequate or inappropriate diet, heightened anxiety and chronic social stress, and other aspects of alienation from labour and life adversely affect health status indicators and drive up the utilisation of health services. What is of special importance about all these factors is that, by definition, they are preventable. Yet, medicine, medical research, and the medical care system continue to ignore the possibility of prevention by not addressing the social occupational, and environmental origins of our current disease structure.

Each of the above points has an underlying economic aspect. The cost explosion in medical care today has established cost containment as the overriding priority in most decisions. With the US economy facing severe problems of inflation and intermittent recession, both corporations (who purchase the bulk of health insurance for their employees) and the Federal Government (which funds services for the poor and aged) are calling into question the amount of money being spent on medical care services (50). The cost of medical care and other associated health services (such as environmental and workplace clean-up requirements) has increased at an exponential rate over the last three decades, making the health sector a leading growth industry. From the corporate perspective, these health benefit costs might have their own justification if the present array of services returned an even larger increase in the labour force productivity via improved heath. But the past two decades have brought significant change in health status, despite this escalation of expenditure. Complicating this problems is the fact that the major portion of health expenditures flows out of the corporate sector and State into the hands of professionals and hospitals. Thus health care expenditure appear unequivocally as a major factor limiting capital accumulation, and a corporate strategy to reduce inflation in health costs is currently becoming evident (51). Replacement of costly, high-technology medicine with cheaper, non-technological therapies is a major redirection advocated by proliferating medical-care evaluation studies (52, 53). Corporations have developed an interest in holistic health as *Forbes magazine* notes, "because it emphasises more money-saving prevention and patient responsibility" (54).

In addition, to the extent that the provision of successful medical care has become a source of legitimacy in advanced capitalism, increasing popular dissatisfaction with current medical practice will become a chief focus of the State (It has become clear for instance, that right-wing political groups have latched on to the public disaffections with medicine through the promotion of anti-abortion crusades, laetrile

legalisation campaigns, etc.).

All of these problems have led to a heightened concern with health in recent years. The holistic health movement has arisen in part out of this concern and in part has helped to generate it.

Holistic Health Movement

There are problems in defining the holistic health movement beyond grouping together all practitioners who place themselves against or outside the mainstream of modern medicine. Further, it is difficult to distill commonalities from the potpurri of alternative therapies, since such a diversity has been linked as a movement by its organisational advocates (1,57-59).

The positive health orientation of holistic therapy has two separate components. The first is the perception of health as a value in and of itself; the second is the notion of health as a praxis—the active participation of the individual in the ongoing maintenance of his/her own helth. Holistic therapies also assume a unity between mind, body, and spirit, the major implication of which is that illness is regarded as more than just physical disease and is assumed to have causes and dimensions beyond the purely biological. The separation of mind and body has long been a philosophical issue in Western thought, and the elimination on downplaying of the mind as a component of the disease process has been considered as of the cardinal success of scientific medicine. The critique of the mind-body duality and the reintroduction of elements of spirtuality in holistic medicine form a strong counter to the crude materialism of scientific medicine in its narrow emphasis on what it takes to be the physical and biological source of disease.

The holistic health movement has philosophically set itself in direct opposition to some of the basic tenets of scientific medicine. The potential power of the "mind" over the "body" is being tested in the treatment of various diseases as practices such as meditation, biofeedback, autogenic training, and hypnosis become quite popular. The exploration of psychic phenomenon (e.g. clairvoyance, telepathy, precognition, psychokinesis, and extrasensory perception) may encourage a new understanding of pathophysiology and ongoing health maintenance. Other practices (such as yoga and the various forms of martial arts) are promoted as aids in forming an integrated view of the individual's health and a greater consciousness of health.

Although it is challenging the taboos of scientific medicine, holistic medicine has not yet established itself as scientific. Holistic therapies primarily have relied upon ancedotal evidence, with "proof" of efficacy to be found in individual testimony. Since scientific theory prides itself on repeatability and universality medicine orientations easily fall prey to charges of quackery and hucksterism. Several factors, however, complicate the picture. For one thing, a number of scientifically established medical procedures and therapies have been found in many cases to be no more effective than treatment by a placebo. This applies not only to certain drugs, but also to various surgical and medical treatments. Indeed, several recent Government reports have criticised the scientific medical establishment for choosing many of its practices more by intuition than by science or study. Most notable is the recent survey by the Office of Technology Assessment, an agency of the US Congress on the safety and efficacy of 17 common medical practices (52). The implication of this orientation is apparent: if scientific medicine were to subject itself to the same rigorous testing that it demands for holistic medicine, many of its forms of intervention would not fare too well either! One may conclude that science, as we presently know it, is insufficiently developed to properly understand the interactions of body, mind, and spirit over the course of the disease process. At the same time, this line of reasoning should not suggest immediate acceptance of holistic medicine and its various therapies without some proof of efficacy.

By concentrating on individuals and tailoring therapies to individual needs and desire, holistic medicine achieves a great degree of client satisfaction. Interpersonal sensitivity and responsiveness to patient's needs ans values which are generally operationalised in the holistic practitioner-patient interface. Since the patient is held responsible for his/her own health (and in many cases, the results of therapy), people are loathe to blame failure of the invervention or the therapy itself. Rather, it is usually assumed that the patient has not tried hard enough, "it's not the time yet," or that the search must continue for the real root-cause of the illness. Often, the power of suggestion and belief plays a dominant role in therapy. For the most part, then practitioners of holistic medicine tend to generate loyal followings for their particular theory and therapy among their clientele. In an era of growing disenchantment with modern medicine, one finds in holistic therapy a popular modality upon which to center one's hope for alleviation, if not elimination, of a plaguing health problem. It is less invasive and dangerous than scientific medicine; it tends to use natural or symbolically ritual medicines or drugs; and because it employs more intimate forms of treatment such as touching, holistic medicine is usually enjoyable and pleasant.

As public support wavers for the scientific establishment, various forms of holistic health care are generating attention and hope from both those suffering from maladies and those wishing to grow in new dimensions of their lives. Nevertheless one finds in the holistic health movement many of the same organisational and social patterns that predominate in the present health care system: solo, fee-for-service entrepreneurial practice; knowledge or skill sold to "consumers" in commodity forms elitist and sexist behaviour on the part of the practitioners; a concentration of availability of services to middle-class, white people able to play; and a clear separation between practitioners and those who are served. Most practices also tend to be focussed on the individual, as in scientific medicine, and lack virtually any focuss on the larger social grouping.

In the midst of the growing narcissism in the United States today, holistic health practices are being explored as part of strivings toward self-growth and self-actualisation (60). In addition, some corportions are beginning to seek increased employmee productivity by offering training in practices such as mediation for stress reduction (61-63). While taking a positive step by including the mind as a causative as well as a healing agent, most holistic practices continue to exclude the external social world from their attempts at healing, failing to provide strategies for changing economic and social relations. Some practices are serving to further commodify

alienation "personal" problems are temporarily relieved as a particular practice tends to adjust the individual to the society from which the pathology has arisen. Thus, this adjustment of the individual may become a prominent tendency (64).

Most holistic practices contain heavy doses of mysticism and charismatic elitism. Their Eastern (and precapitalist) origin often results in an authoritarian elitism that has taken interesting—and—disturbing—forms as these age-old practices have been transplanted into America. The most glowing deficiencies of holistic practices, as they currently exist, arise out of their intense individualism and limited notion of totality. Most assume that they are totalistic by stressing the unity of the body, mind, and spirit. However, this ignores the larger social world outside the body from which much of disease originates. Meditation, for instance, can relieve the effects of stress on an individual, but it does not *remove* the stress source. When one stops meditating, the social stress is still there. A readily apparent weakness of many of the holistic medicine practices is that they ignore politics, declining to connect disease to existing social relations. When these connections are made, the problem is often defined in terms so general—"the West," "modern society"—as to suggest that the only sensible course is exclusive concentration on healing the individual in a chaotic and brutal world. The philosophical thrust of holistic medicine assumes emotional and spiritual dimensions of the individual transcending the physical body. Yet even this expansion still centers on the internal dynamics of the individual to the exclusions of external reality. This, of course, differs from the social medicine of the 19th century, which defined the totality to include the physical and social environment as well as the human organism.

Conclusions

Various holistic medicine therapies are rapidly becoming popular alternatives to scientific medicine. In just a few years, holistic medicine has been able to achieve significant public support in the Western world, as well as the nascent support of both corporations and the Federal Government. It is imperative that health policy analysts and health practitioners understand the nature and content of holistic medicine and the social dynamics out of which it arises.

That holistic medicine poses challenges to the hegemony of scientific medicine cannot be denied. One example is the pressure for the National Cancer Institute in the United States to hold controlled clinical trials to test the alleged efficacy of laetrile in cancer treatment. Some 17 state legislatures have legalised the prescription and sale of lactrile within their borders, a decision made in spite of the almost unanimous opposition of the medical profession. Chiropractic therapy now receives reimbursement from several Medicaid plans and from Medicare. Court cases regarding the rights of people to choose a holistic therapy (i.e, nutritional therapy or laetrile) against the wishes of their physicians, who advocate either chemotherapy or some invasive treatment, have been heard with mixed results to date (see, for example, refernce 65). It seems apparent, though that many more such issues will be fought out in the legal arena. Meanwhile, a groundswell of investigation into alternatives to scientific medicine has been occurring as patients seek out therapies suggested by the multiplicity of articles in the popular press. Bookstores have been devoting higher and higher percentages of shelf space to sections on health, psychology, and the occult; many of the ideas gleaned from this recent explosion in publishing are used by people as supplements—it not direct alternatives—to what scientific medicine-oriented physicians suggest.

Its nontechnological nature and extreme emphasis on individual responsibility for health are aspects of holistic medicine that imply cheaper modalities of care than the present medical care system offers. Those social groups advocating cost containment in helth care have an obvious interest, then, in the explosion, growth, and spread of holistic health care. As noted earlier, medical care inflation has been running at a rate almost twice that of the rest of the economy, and the likelihood of its being slowed down dramatically is quite limited in the absence of major cutbacks in care, which seem politically infeasible at this time. Given this reality, there is a definite political and economic necessity for new approaches to healt and health care problems. Holistic medicine just may fill that need.

Similarly, a changing ideological focus is being promoted in health today. A medical care system emphasising the individual's role in maintaining his/her own health and promoting a significnt lessening of absenteeism among employees would be of considerable value to the corporate sector. It the infusion of holistic medicine modalities into the workplace could keep people on the job and improve their individual productivity by making them either objectivity healthier or at least believing they are healthier, it would serve to address one of the most pressing problems in America today (as defined by corporations): low productivity due to worker alienation. Thus holistic medicine could be of great utility to our present malfunctioning system of economic production.

Finally, if holistic medicine should succeed in giving people a sense of caring for themselves and being the decision-making subject in their lives rather than just an object; if it should succeed in promoting dramatic changes in current, unhealthy lifestyles; it if does provide a more meaningful justification for living in a relatively unpleasant world; then it most certainly will be utilised by greater numbers of people in our society. Yet, by achieving such results, holistic medicine may then become a part of corporate and state strategies for cost constainment in health care. Also holistic medicine could easily be formulated into a social mechanism for allaying criticism of present inadequacies in health care delivery and the social production of disease (66).

We have attempted to demonstrate that the resurgence of the holistic health movement in this decade is no social accident, but clearly arose in response to degenerative social and psychological conditions of the day. Holistic therapies are addressing some of the crises that have been created by the ongoing demise of scientific medicine. It should be noted that scientific medicine is far from dead at the moment, however, and may, with some propitious discoveries, regain its hegemony. At the same time,we have tried to indicate that holistic medicine, to the extent that it focuses solely on the individual and ignores political and social dimensions, is not the entire answer for health either. Nevertheless, holistic medicine is an up-and-coming social movement gaining wide

popular support, and as such, demands attention from all health workers and policy analysts (67-69). This attention should, hopefully, be directed toward uniting people in the transformation of their social conditions necessary for improved health (70).

UPDATE

News and Notes

Privatisation of Medicare: Help from GIC

THE General Insurance Corporation (GIC) has announced the introduction of a medical insurance scheme, named Mediclaim, with effect from November 3. The introduction of medical insurance should ordinarily have been welcomed as an important step towards extending the benefits of modern health care to the mass of the people. However, the scheme announced by GIC through a high-powered advertisement campaign should instead be expected to, and is indeed intended to, give a strong fillip to the privatisation of health care in the country—and this notwithstanding the fact that the GIC itself is a wholly government-owned corporation. In fact, we have here another instance of how the government and public sector organisations closely collaborate with private business for the advancement of the latter's interests.

The manner in which the GIC has chosen to advertise its Mediclaim scheme tells its own tale. The advertisements read very much as if what is being advertised is a sort of lottery: "Claim medical expenses upto Rs 17,600 a year by paying just Rs 250", the GIC proclaims. Also noteworthy is the prominence given in the advertisements to the fact that the premium paid on Mediclaim policies will be deductible from taxable income under section 80D of the Income Tax Act, making it clear that the GIC is aiming the scheme mainly, if not wholly, at income tax payers who constitute some three per cent of the country's population.

In any case, the terms of the Mediclaim scheme are such that there is no possibility of anyone except the very well-off benefiting from it. The GIC is offering five classes of policies. The annual premium on the least-priced two are Rs 250 and Rs 350 and entitle the insured person to claim 80 per cent of the cost of medical treatment in hospitals subject to a maximum of Rs 17,600 and Rs 25,500, respectively. Under these policies the GIC will pay nothing if the medical expenses are not incurred in a hospital but on treatment at home. Then there are three other more expensive classes of policies, costing Rs 600, Rs 840 and Rs 1,300 per annum, which entitle the insured person to reimbursement of hospitalisation expenses upto Rs 37,750, Rs 52,750 and Rs 82,500, respectively; in addition, under these policies medical expenses incurred on treatment at home too will be reimbursed upto Rs 5,250, Rs 7,400 and Rs 11,500, respectively.

At first sight, the premium rates may not appear excessive. The catch lies, however, in the fact that to be meaningful medical insurance must cover the whole family. Taking a family of five members, the two cheapest policies, which cover medical expenses only in case of hospitalisation, will cost Rs 1,125 and Rs 1,575 per annum, respectively (after allowing for the 10 per cent discount which the GIC is offering where one or more dependents are also covered). At the other end, the premium on the more expensive policies, which alone cover the cost of domiciliary hospitalisation, vary between Rs 2,700 and Rs 5,850 per annum—quite large sums even for those in the upper income brackets. No wonder that the GIC has realised that it desperately needs the crutch of tax deductibility of premium payments to be able to sell Mediclaim. Incidentally, by its very nature, private medical insurance of the type being offered by GIC tends to be expensive. As a result, it can be meant only for a small select section of the population. Even in a country like the UK, according to one estimate, whereas nearly a quarter of professionals have private health insurance cover, for semi-skilled and unskilled workers the coverage is less than two per cent.

If, on the one hand, Mediclaim is meant to cater to upper-income income-tax payers, on the other hand, it is intended to cover the cost of medical treatment in the exclusive private hospitals set up as corporate business enterprises, the rapid proliferation of which has been one of the major developments in the area of health care in the country in the last few years. This is evident from the fact that the hospital room charges that Mediclaim allows for are Rs 550 and Rs 350 per day for the two most expensive policies and Rs 250 per day for the remaining three types of policies. Of course, there is in this country a class of people who can without batting an eyelid pay for treatment at the new private hospitals at these or even higher rates. But it is naturally a small class. So if the private sector hospitals are to continue to attract the required large investments and their number is to continue to grow and their profits are to keep rising, the demand for their services needs to be enlarged beyond that provided by the above-mentioned class of the very rich. This is precisely what GIC's Mediclaim scheme aims to do with the direct help of the government in the form of tax exemption for premiums paid under the scheme, which amounts, roughly speaking, to between one-third and one-half of the private hospitals' charges being paid out of the public exchequer in the form of tax revenue forgone. It should by now be clear how

the government and the public sector GIC are aiding the privatisation of medical care in India.

The GIC's Mediclaim scheme is only one of a series of recent moves by the government to help privatisation of medical care. In December last year the Income Tax Act was amended so that reimbursement by employers of medical expenses such as operation fees, hospitalisation charges, cost of medicines and tests, etc, incurred by employees and their families is no longer treated as a perquisite. In other words, the amounts so reimbursed are not now added to the taxable income of the employees. The term 'employees', it has been specifically provided, is to include "managers/directors" (with their families). The Income Tax Act 1961 already permitted government employees to receive such tax-free reimbursement of medical expenses. This benefit has now been extended to those working in the private sector and in public sector undertakings.

The change in the tax treatment of expenditure on medical expenses has to be seen together with some other decisions of the government to appreciate its full import. Under the scheme to encourage non-resident Indians (NRI) to invest in India, hospitals have been included among the areas qualifying for NRI investment upto 74 per cent. Later the definition of hospitals was enlarged to include 'diagnostic centres' as well in order, as the government press note on the subject put it, "to facilitate the inflow of NRI expertise and investment in the area of medical diagnosis through specialised and sophisticated equipment not readily available in India". Apollo Hospitals in Madras was the first to come up in response to the government scheme, as a public limited company with non-resident investment. Others have since followed in its wake.

In addition to these specific measures to facilitate their growth, the government is only too ready to give the private corporate hospitals legitimacy and respectability. For instance, while inaugurating its Diabetes Foundation, the Vice-President of India acclaimed Apollo Hospitals as "the first fully-equipped, corporate, multi-speciality hospital in India" and added, "I have had the privilege of being associated with the development of this unique all-round medicare facility". What followed was even more explicit underwriting of private medical care at the cost of the facilities provided in government hospitals. The Vice-President said that to depend on the government alone for health services would be to reconcile oneself to mediocrity and paucity of such services. In other words, because government health services are of indifferent quality and inadequate, the government needs to support private establishments such as Apollo Hospitals.

This is a piece of deliberate misrepresentation, for the high-cost private sector hospitals with their high-powered doctors, their sophisticated diagnostic machines and therapeutic aids provide an altogether different type of medical care from that provided by the government health services and to an altogether different class of people. Far from making up for the undoubted deficiencies of the public health services, privatisation of medical care with the active support of the government is bound to further distort the priorities of the government's health policies and thereby further choke the flow of resources and qualified medical personnel to the government health services, rendering them even more unequal to the task of providing health care for the mass of the people.

Legislation of Abortion in Yugoslavia

Yugoslavia is a country where abortion is legal and very simple. It is sufficient that the woman chooses the hospital and the gyneacologist, pays about 50 guilders for the whole treatment including the anesthesia, and she is back home the next day. All this is due to the very good laws and to a struggle that the women of Yugoslavia won fighting against the conservative behaviour and practice. The struggle for various women's rights including the right to decide about her own childbirth, dates in Yugoslavia from the second world war. In 1952 the interruption of pregnancy was legalised but only for medical reasons. The social reasons were accepted too. From 1960-1978 the abortion had to be approved by a commission, instead of the woman herself. Various commissions had different opinions, which made it impossible for women to use their legal rights. Although the commission approved of 97 per cent of the petitions, in order to lessen the tension for women and to liberate them from the haste, and all the waiting in the medical clinics, women still made further efforts to liberalise the law even more.

A new law was passed in 1978 and according to it the decision about childbirth is a personal matter. A part of the law is about contraception: the rights of people to learn about contraception and the planning of the family is acknowledged. Sterilisation is allowed for persons older than 35 or if there are other medical reasons. The main feature of the law about abortion is that every woman has the right to ask for it, that they are safe financially, and institutions are available, which is very important. And that abortion can be refused for medical reasons. The law makes it possible for a woman to have the abortion after a medical examination on her request, till the 10th week of pregnancy. From the 10th to 20th week and later it is possible only if the commission finds it not dangerous for the women's health. Persons under age can also ask for it, but with the agreement of parents or the person responsible.

After bringing up the free law the number of abortions has increased a great deal, which is alarming considering that Yugoslavia has about 22.5 million inhabitants and the number of abortions done annually is about 300,000. There are some parts of Yugoslavia where the number of abortions is larger than the number of births. In Servia there is one birth to 1.4 abortions, in Croatia one birth to 0.75 abortions. And it is still increasing.

In Yugoslavia contraception is not very popular, there are not enough services for it and young people are not well-informed about it. Although the number of services is increasing, only 40 per cent of the women use contraception. A lot of women still use abortion as the only method of contraception together with the traditional methods—39,000 abortions have been done on married women out of 40,000 that were done in Croatia. The figures tell us that the planning of the family is not valued. Sterilisation is very unpopular, men do not ask for it at all.

Fifth International Women and Health Meet

WOMEN health activists, researchers, and practitioners form all over the world will gather in San José, Costa Rica next spring for the Fifth International Women and Health Meeting. The Centre Feminista de Informacion y Accion (CEFEMINA) is co-ordinating the planning for the conference, which is scheduled to take place from May 23 to 28, 1987. This marks the first time the meeting will be held in a Third World country; the previous four meetings have been held in European cities.

The conference will focus on five main themes: population policies and reproductive rights; community health; environmental health hazards; drugs; and the health care system. The organisers welcome any suggestions for specific workshops to be organised under these categories as well as general input into the planning of the conference. Meetings will be held in Spanish, French or English, with simultaneous translation available for plenary sessions. Childcare facilities for participants' children will be provided.

The conference organisers also urge women who want to attend to begin fund raising immediately to cover travel costs and expenses. Those who can are encouraged to help raise funds for women who cannot cover their own costs.

Eleven national and international women's organisations, including Isis International and the Latin American and Caribbean Health Network which we co-ordinate, are sponsoring the conference. The others are Peru Mujer, Centro Ecuatoriano para la Promoción y Acción de la Mujer, Women's Global Network on Reproductive Rights, International Baby Food Action Network, Health Action International, SOSHIREN Tokyo, Isis WICCE, Dispensaire des Femmes, and the Boston Women's Health Book Collective.

For further information please write to:
CEFEMINA, Apdo 5355, San Jose 1000, Costa Rica.

Ills of Public Hospitals

Recent events have drawn fresh attention to the atrocious state of public hospitals all over the country. The glycerol tragedy which is unfolding every day in the courts in Bombay can well serve as a case study of the degree of inefficiency in these hospitals. Even more disconcerting is the fact that the doctors and the officials appear to be exhibiting a degree of nonchalance which can only be termed inhuman and callous. Officials have admitted that no action was taken other than issuing a routine alert, and that after a delay, even though several similar deaths had occurred in a single ward; doctors have confessed that they did not deem it important to read circulars marked urgent; and units have been found to have continued to use the same batch of suspect glycerol for 48 hours after an order was issued to impound the batch.

It was around this time that the doctors at KEM hospital in Bombay went on unique strike with the sole objective of highlighting the utter lack of adequate and necessary facilities in the hospital. And what they had to tell the patients was indeed a revelation—substandard equipment, operating theatres with fungus growth on the walls, machines sitting idle for want of simple repairs, shortages of drugs, and so on.

However, all this attention on the inefficiencies of public hospitals has given rise to a feeling that the only choice then is to make use of private practice facilities, even if one has to foot the fabulous bills later on. In fact, state governments, like Uttar Pradesh have already set in motion, plans to hand over rural health care to private sector.

There cannot be a more mistaken notion than this. The roots of the malady in public hospitals probably lie in the proliferation of private practice and private hospitals. And it is these hospitals which have received enormous support and patronage from the government even as the government-run institutions have lacked both finance and other support. There is need to look more closely and critically at the relationship between the private and public institutions. Today the state is openly admitting its inability to provide welfare services such as health and seeking to move its responsibility to the private and voluntary agencies. Can the government abdicate its responsibility to provide 'welfare'—even if it is rudimentary? Have we as health activists been altogether more concerned about evolving alternatives than with pressurising the government to be accountable?

Female Patients versus Male Doctors' Universe

jytte willadsen

How does medicine view women's health problems? In recent years the women's movement has posed many questions to medicine which has in turn set the medical establishment thinking. This article is an 'insider's view by a Danish woman psychiatrist and discusses how bias influences both the diagnosis and the treatment of women's problems.

SCIENCE is unscientific in the way it analyses and treats women. Virginia Woolf says, "Science it would seem is not sexless, she is a man, a father and infected too".

It is very important and essential to confront the medical world with feminist viewpoints. You may then be able to explain many otherwise unintelligible problems and treatments. If we raise the consciousness about this confrontation we can go ahead in a much wiser way and otherwise we will obtain impossible results in the treatment of women patients. In the industralised part of the world women live about seven years longer than men do. Why is it so? On the other hand, depressions are much more widespread in our societies among women, and women are depressed between three and six times as often as men. What's the explanation of this? Women go to see their doctors twice as often as men. Is this good or bad? Women are drugged twice as often as men, and many healthy women are constantly under the control of an artificial intake of sex-hormones, while healthy men as a rule don't take hormones. Why is it that men most often abuse alcohol and drugs? Why is it that nearly exclusively, men are imprisoned?

Women's Biology

Women have a wonderful biology. Our life is cyclic and cyclicity is an underestimated richness. From puberty the woman is constantly changing. She is influenced by a hormonal balance which all the time changes quietly, little, just like the moon and in the same pace as the moon. Every 28th day women menstruate and after this, in the middle of the period, we are in ovulation. After this and before the next menstruation we have the premenstrual phase, where many women feel extra energy, extra power and vitality. During menstruation many women feel their womanhood confirmed and sealed. Some times the female cyclicity takes other forms. When you are pregnant you are in a long cycle of nine months, where you feel new changes, new hormone balances controlling your organism and from moment to moment you and your child are in quiet change and movement towards birth. The birth itself is a series of oscillations and the labour begins quietly and slowly. As the labour continues the oscillations become more and more intense, until the child is born. Afterwards a new cyclicity arises and you find a new hormone balance with new experiences. When you nurse the child, your breast slowly fills up and afterwards your love to the baby slowly and peacefully empties the breast again. This sort of cyclicity continues until you again return to the ordinary cyclicity and the ordinary menstrual cycle. May be after more pregnancies with ordinary cyclicity in between, you at last reach the 'large' cycle, the climacteric, where you experience the menopause and your organism again reaches a new hormone balance in quiet pace. For some years you then will go on this balance until old age and death.

The female doctor and psychoanalyst Therese Benedek wrote a paper, 'Climacterium a Developmental Phase'(1950). She found that psychodynamically the female sexual cycle involves a greater integrative capacity within the personality. Thus when the approaching menopause diminishes the fulctuations of the sexual drive, the ego is flexible enough to use the energies released from previous tasks for new integrations. In other words, the female cyclicity is an advantage because it creates flexibility to manage new life situations and use the energies in a new and satistying way, as may happen in the climacteric.

Margaret Mead talked about the postmenopausal zest and as you know she herself enjoyed her zest and many of her world famous works were made in her postmenopausal phase.

Karen Blixen, Danish female author, wrote in *The Caryatids, an Unfinished Tale* (1957), "He watched the figure of his wife, sunk in musing in the carriage seat. He recognised the thoughtful mood which had come over her, the wave-motion of her being, following the rhythm of the moon like the tidal waves of the sea. It was as if a weight was being gathered grain by grain, within the depth of her, balancing down her vitality into a new calm and a deeper understanding. Sometimes she would disappear from him altogether for a day or two, but only to come back, radiant, as from a flight into a distant world from which she brought with her fresh flowers to adorn her home." When we talk about the female cyclicity, the phases in our lives, in this way, it is difficult for many of us to recognise ourselves. Also in my daily life, femininity is quite different from the way I have tried to describe it here.

Menstruation

You see the problems clearly in advertisements. An ad from a Danish paper "Girls! Be balanced every day! Menstrual days and the climacteric don't need to be problems! Take the new Melbrosia pill every day." The advertiser trusts in our imbalance and especially in that we feel it.

In an ad for doctors, the drug company offers hormone therapy for premenstrual syndrome (PMS) and the pill is said to remove irritability, crimes, accidents, breast tenderness, emotional turns, headache and so on. This is an audacious claim by the drug company, because premenstrual syndrome lacks scientific proof. In connection with this ad we had a debate in the Danish media. Female doctors emphasised that crime and accidents primarily are male problems and that it was farfetched to believe that women should need treat-

ment with hormones to prevent crime. After a long debate the company at last admitted that the ad was not objective and it was then withdrawn. In a mass-circulating newspaper a cartoonist showed his new understanding—his cartoon showed a battered woman calling the drug company, "Can't you produce some similar hormones for my husband—but they have to work every day." *Menstrual troubles: Symptoms, course of disease, treatment*, is the title of an informative book for all women. It was published after the debate, and the author is one of our prominent gynaecologists. From an illustration in the book you see the endometrium changing through the period. At the top of the picture is an illustration showing how the woman feels. She looks free and well until the last days before menstruation. Then she is shown to be sitting down and she looks like a person who is unable to do reasonable things. It is interesting to look at this picture and at the same time be conscious of the fact that this is never scientifically shown to be a normal situation for women. Some healthy women can feel negative sensations in the days before menstruation, but other women can feel the opposite or nothing and this is totally forgotten in medicine.

In medicine a woman is regarded as a handicapped man. It is considered a negative factor that she may be premenstrual or menstrual or in ovulation and that she may be pregnant or in puerperium and for a certain period she may be nursing and later she will experience the worst, the menopause. A women is thus always in a 'special condition'. She is never okay, but what about the original model, the man?

Some female doctors have studied 'the man' and we plan to publish a book with the title, *Testosteron troubles: Symptoms, course of disease, treatment*. As yet nobody has taken care of the poor man with this strained condition. We will stress, that the level of the man's testosteron concentration in blood is nearly always the same, and as everybody knows, men are always in the same spirit. But many men suffer from testosteron poisoning, and they are in the same aggressive condition all the time. We hope very much that we can help them, but until now we have no sure and certified method of doing it.

Giving Birth

In Denmark nearly all women give birth in hospitals and both the labour and the condition of the child are monitored in several ways. It is difficult to imagine how women giving birth will be able to experience the many sensations and great moments in their lives, when they are treated as patients in the hospital milieu. We know that women nowadays are at a larger and larger risk of having to undergo Caesarian sections so that their experience of giving birth will be an experience of being under narcosis. And what about the children? Is it good for them to come into the world and live without the normal experience of birth? Of course it is advantageous that we have the possibility of a Caesarian section when it is really necessary, but is it with advantage that we perform the operation more and more?

Climacteric

In ads for the climacteric the drug companies tell us that we can do something for this otherwise hopeless situation. Hormone therapy solves the problems. The atmosphere in illustrations is depressing and resigned and often against the background of rainy weather or autumn.

In Denmark two well-established male gynaecologists have written an 'informative' book about the climacteric. It is issued in the same series as the book about PMS mentioned above. The title is, *The Climacteric: Symptoms, Courses, Treatment*. The book has illustrations presenting the woman before and after the menopause. You see a profound change between these illustrations. The postmenopausal woman is fat and her appearance is totally without charm. We must wonder why male doctors want us postmenopausal women with zest to identify ourselves with such pictures of women.

The diagnosis of the menopausal syndrome was first introduced to English-speaking doctors late in the last century, and it became an instant success. Joel Wilbush (1981) in an article, "What's in a name? Some linguistic aspects of the climacteric " views the diagnosis of menopause as a 'wastebasket' and the introduction of this diagnosis in the last century gave little offence. It was an excellent label which satisfied doctors and patients alike.

It is important to stress the lack of proof of the connection between mental illness and menopause. In Sweden Tore Hällström (1973) undertook a thorough epidemiologic study of 800 women and found no correlation between the menopause and mental disorder. In Denmark, a study including all patients in the psychiatric institutions has shown no peak in the number of patients in the middle years per number of inhabitants in the same age group. Weissman and Klerman (1977) in a comprehensive review of the literature concluded that there was no evidence that women are at greater risk of depression during menopausal period.

Many men and women feel that menopause is the worst experience in the life of a woman. And some even claim, that it will leave her as a castrata for the rest of her life. In the treatment of menopause the most important task of the doctor is to give the women careful and factual information. It is necessary to distinguish facts and myths. I would like to stress once again that no mental disease has ever been proven to be caused by the menopause. Therefore hormonal treatment cannot be expected to, and has never been proven to alleviate such diseases. When the woman is well informed it is up to her to choose whether and for how long she wishes to have hormone therapy. The informed choice of the woman is much preferable to an authoritarian decision by the doctor.

Depression, Thy Name is Woman

Now let us take a look at depression. Depression is a 'woman's disease' and it is up to six times as common among women as men. Today most psychiatrists and psychologists agree that we see quite smooth transitions from the normal sorrow to very deep and serious depressions. The psychiatric diagnostic apparatus is here, as in many other places quite uncertain and unstable. In all the professional textbooks you find the description of the depressive person as passive with lack of initiative, lack of self-confidence, introjection of aggression with subsequent feeling of guilt and with a lack of sexual desire and performance, men are impotent and

women frigid. Here it's essential and interesting to remember Freud's description of the normal woman and after him, many other identical descriptions. Freud tells us that the normal woman is passive with lack of initiative, lack of self-confidence, as a rule she introjects her aggression and she cannot show her anger, is inclined to feeling guilt and sexually she is masochistic. As you can see the two descriptions are rather alike. Indeed they are nearly in accordance word by word. Yet the normal woman is labelled as masochistic, which I think many feel is worse than the depressive woman's frigidity.

Freud's and other description of the woman is, I'm sorry, current also today. Women's sex role is a norm which in many ways demands passivity. When passivity is pronounced, depression will follow. It is more than hypothesis that the female sex role in many cases is the same as mild depression. And when the woman experiences psychological traumas, strain and so on, she overplays her female role as a defence and then she develops a more severe depression (Willadsen, 1983).

The bringing up of girls is an upbringing to passivity, to potential depression. In many situations it can be easy to be passive and it is important to understand the tempting aspect of convenience of the female sex role. You can identify female passivity and helplessness in many ways.

Have a look at the language. Sheila Rowbothan says in *Woman's Consciousness, Man's World*: "As soon as we learn words we find ourselves outside them. We need a language which constructs the reality of women's strength, women's power. When you are angry and want to express your strength and power, you have not your own words for it".

The normal result of the normal upbringing of a girl, is a mild, attractive and kind woman and whatever happens she will stay by her man. Often she cannot manage to accept this normal sex role, and cannot find her psychic balance, and then, nowadays, very frequently she ends up a depressed woman. The depression is for her a flight from an intolerable life situation and in the depression she can relate to her surroundings although in a negative way.

Hysteria

In other cases the women ends in another exaggeration of the female role, the so-called hysterical personality. In the leading Danish textbook of psychiatry our first psychoanalyst (Vanggaard 1985) as late as last year writes about the classical hysterical personality, "A known example is the colourful, lively, attractive and seductive woman, but it turns out that she is not serious. In intimate sexual relationships she is frigid. Even outside the narrow erotic sphere the inviting, charming and seemingly emotional attitude of these persons can impress people—often resulting in disappointment at a larger moment." The editors of the textbook, five other male Danish psychiatrists, all in high positions, have not commented on this outpouring. You see the alarming distance from women's reality. It's the same in many well-known international textbooks.

In the USA's diagnostic statistical manual, the commonly used diagnostic system in the States, DSM III, the term hysterical personality is abandoned and it is now called 'histrionic personality disorder'. In the description in the manual you see that the histrionic personality is described in the light of the usual oppressive concept of women. There you read that histrionic personality disorder is diagnosed far more frequently in females than in males. Such individuals are typically attractive and seductive, superficially charming and appealing. They are demanding, egocentric, and manipulative. They may be sexually unresponsive and in both sexes overt behaviour often is a caricature of femininity. All these pejorative descriptions are known in all sorts of psychiatric literature. The hysterical or histrionic woman is accused directly of looking lovely and being attractive and, at the same time, of being unreliable in their sexual accessibility for men. They bypass the traditional norms and are accused of using the femininity in order to manipulate the surroundings. The textbooks forget the simple fact that behaviour that is rewarded will be promoted. The behaviour of the hysterical women is, of course, determined by their living conditions. The essential issue is the deleterious lack of real female life realisation. Hysterical symptoms act as a substitute and they can be regarded as a caricature of the demands to women's behaviour in general and her sexual life in particular. Hysterical symptoms are distorted communication with the surroundings and an attempt at protest against the conditions. The hysterical person lives under the motto, "Don't think, don't know, don't feel". You have to act as another alien person and to satisfy the needs of other instead of your own, and at that be so kind as not to see through it.

In the Danish textbook the psychoanalyst also writes about the spouses of the hysterical patients. He finds it surprising what many spouses are willing to acccept the hysterical personality. There is really no basis for surprise. Lawrence Durrell formulates so shrewdly: "We get the partner who corresponds to our own inner ugliness, i e, when we look for a partner, our negative aspects will be decisive, while the positive aspects will be without any consequences, because they will be accepted by everybody. The hysterical woman will often marry a special type of man, superficially he is clever and permissive in relation to her, but if you analyse the relation, you will often understand that he plays his own game. For his own good he keeps to the hysterical because he experiences himself as strong and important and as safe as possible in his male role. At the same time he 'fixes' her symptoms because he can't do without.

The label frigidity is often linked to the hysterical. Sexologists have tried to replace frigidity with general sexual dysfunction of the female. They have tried to be progressive, but in vain. Frigidity is essentially the women's skewed protest against participation in the traditional sex life, when everything is dictated by the wishes and needs of the man. She experiences all of it as an attack against her integrity. Many womens suffer from lack of sexual life realisation. The woman's common inclination to passivity explains that she often finds herself to be, what we call, frigid or suffers from sexual dysfunction.

I have read Sheila Kitzinger's *Women's Experience of*

Sex (1983) with great profit, and in many ways I agree with her. She writes in the postscript that she has learned much from writing the book. Before writing the book she took it more or less for granted, that sex therapists must be right when they talk about female sexual dysfunction and when they often use therapies to help women adapt without questioning the social values and codes which impose on us particular kinds of sexual behaviour and assumptions about sex.

It's a fact that nearly all diseases occur with a skewed sex-distribution. In every textbook you find the unequal sex-distribution mentioned. But without any analysis and without recommendations for prevention and cure of the diseases in this light. Drugs are used widely and it is alarming that many, many healthy women are medicated in several ways. In gynaecology, hormones, as I mentioned before, are often used in the treatment based on myths about women's biology and sexual life. The same happens in some cases of gynaecological operations. In general practice the treatment very often is a drug treatment and it is the general practitioners who prescribe most of the psychotropic durgs. Most of them are sedatives but they also issue many prescriptions for antidepressives and neuroleptics.

The pharmaceutical industry is aware of the sex of the doctor and the sex of the patient,. In the ads you often find the attractive woman, with a nice hairdo, make-up and posture and the elderly grandfather-like doctor—he usually has grey hair and a bald spot on top of his head just to inspire confidence. If his patient is a hysteric who cannot manage her frigidity or a depressive who suffers from passivity and lack of self-confidence, where can she go for better treatment, than to the psychotherapist?

Many patients feel that the psychotherapist puts them back in their box and not to a worthy life outside the fixed conventional role. The male society makes its demands. A woman has to be the good wife and mother and at the same time she is expected to be attractive and be able to manage competition from pornography.

Can men (as psychiatrists or doctors) treat women? It is a difficult question, because it depends on the scope of the treatment. In the treatment of the weakest patients it necessary to work with very limited purpose. It's a sort of camp hospital treatment at times where you cannot free the patient from war. If the possibilities are better and the woman has resources and can depend on a supportive social network, then she can go ahead and develop her personality. I'm sure she needs help from others who understand her suppression. Some few male doctors do, and honestly many female doctors do not. We are educated in the male medical world and we have internalised so much.

Voluntary helpers and self-help groups sometimes can be good solutions for women with psychic problems, but often they have very few resources. It can be difficult to offer the necessary steady help. The society should on one side support the pioneering initiatives and on the other side, learn from them and transform the established treatment apparatus accordingly. More importantly than appropriate treatment, we need to raise the woman from childhood to a realistic concept of her own biology and psychology. Then she will appreciate her cyclicity and not be apt to biologise her problems, and more or less unconsciously overplay the normal sensations in the female biological cycles. We need to be conscious of our problems and try actively to solve them. We will define our femininity ourselves rather than to accept the traditional definition put forth by men.

When we meet psychic problems, it's necessary in the earliest phases to be active, to take responsibility for ourselves, to use our anger and aggression and not to introject all of it. In every way we have to counteract the objectification of women in our society. I think our sex life is most important. We must be aware of our sexual position.

Clara Thompson (1942) wrote, "The characteristics and inferiority feelings which Freud considered to be specifically female and biologically determined can be explained as developments arising in and growing out of western woman's historic situation of underprivileg, restriction of development, insincere attitude toward the sexual nature, and social and economic dependency. The basic nature of woman is still unknown." The basic nature of woman is still unknown, we must acknowledge. We owe our children, our species to discover it. We need to think, to know, to feel, if we dare, and if we manage it will give our species a much-needed survival value.

[Paper read in a slightly modified form at the 2nd International Feminist Bookfair, Oslo, June 21-27, 1986]

Organising Doctors: A Difference in Approach

Sujit Das

ANANT PHADKE (*SHR*, II (3) p 151-2) in his critique of my article (*SHR*, II p 57-66) has chosen to employ rude words e g, "shame-faced defence of the interests of the doctors". Rude words may have their appropriate uses but, as I am inclined to believe, are never known to be good substitute for argument. To confess, my article has not been intended to be any sort of defence of anyone and I have not happened to feel any sort of shame in informing certain aspects of a certain section of the medical profession which is yet ill-understood. Reading Phadke's own article (*SHR*, II (3) p 198-50) on the same topic I find I can identify the difference between our basic approaches to the problem but before that let me clarify a few minor points raised by him.

Phadke takes me to task for my original title "Medical Profession in Health Care" which the working editors thoughtfully changed to "Doctors in Health Care" in order to, I presume, save me from ignominy. Phadke claims that the "medical profession being only doctors" is a popular but mistaken notion and it should include nurses, social health workers, etc. On the other hand, I had no intention to suddenly change a popular category of almost universal usage and if I did, I am sure, would have invited another, irrelevant debate. I do not feel much enthusiasm to emulate the purists' example of using the word 'doctor' for only medical doctors which is also a popular but thoroughly mistaken category. Phadke insists that general practitioners should be said to be involved in "petty commodity relations" and not "precapitalist mode of production" because the former is a "part of a capitalist social formation". Frankly, I do not understand the significance of the difference between the two. The production relation of the GP is neither capitalist nor post-capitalist and further, it is also a part of pre-capitalist social formation.

In his own article, Phadke deals with the subject from the traditional and over-worked idealistic approach to which I alluded in my article: "The profession has hardly been looked into as what it is, but often analysed on the basis of what it should be." That is why, Phadke wants to organise the doctors towards the end of fulfilling the tasks set by his own lofty ideal. He starts by uncritically superimposing the formulation of a particular western school of analysts on the Indian situation. This school categorises the highly skilled wage earners of advanced capitalist society as "new middle class" and Phadke adopts this formulation to place the Indian wage-earning doctors to that class and therefore attributes them similar contradictory role towards social revolution.

This he does without even a cursory glance to the Indian reality. By no stretch of imagination could the Indian society be labelled as an advanced capitalist society. The section of Indian wage-earning doctors is yet to be consolidated in a well-defined social layer. In my article, I have briefly narrated the social events which tend to show that this section of doctors is in the process of consolidating towards a distinct social layer, quite different from the other sections, under the influence of objective forces—particularly economic and political—despite individual tendencies to the contrary. Again, I find that Phadke's assignment of these doctor's role in the function of Capital (according to the same formula of new middle class of developed capitalism) is at variance with reality. I have not found these doctors, as a class, performing "the function of capital, of supervising, extracting work from the paramedics" in order to earn a part of the surplus value (from unidentified source). In fact, the current trend shows different picture. In Bihar, UP and West Bengal, this newly organising band of doctors has joined hand with the already unionised hospital workers in common struggle on common demands—particularly trade union—and democratic rights. Phadke 's estimate that these doctors earn a "comparatively high salary" also appears, devoid of clarification, to be another borrowed assumption. With whom has this comparison been made? With employees of the lower hierarchy, or with employees of the same hierarchy or with their work value/utitlity value/market price?

From this dubious promise, Phadke asks the left "to determine its strategy of organising this layer of doctors." He castigates the leadership of the doctors' organisations for organising them on a trade union platform; discounts trade unionism itself as unworthy because this will only consolidate their already earned privilege; laments that there is no "well thought out strategy in organising doctors; and calls for appealing towards a small section of enlightened doctors "on the basis of comprehensive revolutionary medical programme which asks doctors to throw away their privileges as elite doctors in return for the promise of decent, meaningful working life."

Well, there may not be nobler ideal and more humanitarian appeal to the heart and conscience. But such idealistic approaches have never helped. Trade unionism does not owe its origin and development to anyone's desires and wishes. Trade unionism develops from objective compulsions. Economism is one of the primary driving force behind trade unionism. Forgetting that we live in a country where even the mature organised working class itself is bogged down in economism, Phadke is so angry with doctors' trade unionism that he admonishes me for giving importance to the West Bengal doctors' movement in 1974 which did not raise any slogan in the peoples' interest. I do not understand why narration of fact or event should be taken as shame faced defence? Rather I believe it is of no use theorising without a look at facts and events. True to his disinclination to face facts, Phadke has missed an entire paragraph in my article where I narrated the subsequent events revealing how the doctor's organisation later came to understand the linkage between economic aspirations and egalitarian health care service and raised, an entirely new set of demands voicing people's interests.

Contrary to Phadke's assumption, I have not tried to determine doctor's role in social revolution—certainly not at this stage. I wanted to draw an eventful picture of a sec-

tion of the medical profession in the perspective of hard reality. Because I found that the observers almost always dealt with the medical profession from individual presumptions and pre-determined positions without bothering to sift empirical findings. Even the bitter critics of doctors have fallen prey, perhaps unwittingly, to the concept of noble profession and, for no coherent reason at all, expect the doctors to remain unaffected by the nuances of the commercial society and to conduct themselves as holy men. Hence, the exploitative practice of the doctors which is an utter contradiction to the ideal of noble profession, shocks them. Why should the noble doctors behave as other wage-earners do? Why should they indulge in trade unionism and economism as the common workers do? Why should they demand 8-hours duty as everyone does? Why shouldn't they, as noble ones, "throw away their privileges as elite doctors in return for promise of decent, scientific, meaningful working life", as the other commoners do not do? When these doctors do not oblige, Phadke goes searching for a "small critical mass of doctors" who may persuaded to raise a sufficiently strong clamour for "a revolutionary change" in the medical system.

I have little hope he will find one and even if he is fortunate to find them, his ideal may remain unrealised. One thing is certain. We cannot run a medical system without doctors—certainly not by a small critical mass of revolutionary doctors. Before jumping ahead to determine the role of doctors in social revolution, let us try to understand and determine their role in health care. What role do we envisage for the doctors in today's health care? What are they performing? What are the nature and cause of short-comings in role performance? What changes should we demand and strive for in the medical system and what will be the role of the doctors in such dynamic situation? In order to find answers to these questions we have to purge ourselves of the myth of noble profession, step out of our idealistic world of believe and turn a fresh look towards doctors as just a social layer with the relevant particularities. We have to collect real life data and analyse them. We have to know how the doctors practise medicine in the state hospitals, how they, as a class or interest group, interact with the recipients, non-doctor workers and the employer. In this context, discussion on professionalism, role expectation, role performance, as well as agitative movements become relevant.

When we do this, we may be able to understand and determine the service-doctors' role on the basis of their own conduct and not through any wishful thinking. Then only will we be in a position to determine their relationship with a people's health movement for a just health care service. The relationship—I quote Thompson again – "must always be embodied in real people and in a real context".

Without going into details, I may draw attention to the experience of USSR and China. There, in the post-revolutionary period, the state had to deal with the entire medical profession in reshaping health care service. Revolutionary exhortations were found to be inadequate. The instrument of incentive and disincentive was ultimately resorted to and it brought results. The problem has yet to be resolved. Professionalism, job satisfaction, economism, role expectation, role performance, private practice, technocratic scienticism etc, are still living problems.

Light on 'Blind Spots'

u n jajoo

ANANT PHADKE in his review (RJH, June I: 1) of our book *When the Search Began* contends that: "It is not clear from their account as to why the response to this scheme was better than to the earlier one. No economic or political activity has been reported. Perhaps the support of the medical college including the doctor's monthly visit made this difference."

This and other such statements need some clarifications. The insurance scheme demanded Rs 3/person/year as contribution from 75 per cent of the village population and offered hospital services at 75 per cent subsidised cost (See Introduction). Though highly subsidised, hospital charges were beyond the reach of poor villagers. The Jwar Insurance Scheme provide free hospitalisation for all unexpected illnesses and thus provided a sense of security. It was essentially this modification which attracted people and not any economic or political activity.

Regarding Phadke's comments on cost analysis, a close look at the cost analysis will reveal the following:

Hospital indoor admission rate per year = One per 10 population
Government expenditure for 10 people 28×10 = Rs 280/year
Contribution from the people = Meets the cost of peripheral health infrastructure plus spares Rs 18.50
Therefore the amount which can be spared for hospitalised treatment per patient = Rs 280 plus Rs 18.50 Rs 298.50

With a proper referral established between the hospital and the specialised care hospital, I feel that with the amount available, and health insurance coverage for indoor admissions can be provided. It is futile to compare this cost-analysis with existing government PHC set-up where distribution of funds provides only 12 paise/person/year towards drug cost. What is important I believe is that the alternative strategy appears feasible.

Elsewhere Phadke comments that the increase in percentage coverage for health insurance from 46.5 in the first year to 71.5 per cent in the third year does not tally with the earlier claim. The data quoted earlier is from village Nagapur—the village where by trial and error health insurance scheme evolved over the years. The data on increase in coverage (on page 14) is pooled information from the new villages where health insurance scheme was introduced and then implemented once it was found feasible. The strategy of our entry

in village life was totally different.

As for the 'blind spots' the search continues. We began with what was possible in the given social structure, involving people to the maximum, without corrupting them with blind charity. The 'blind spots' can only be eliminated when really democratic health services evolve. What matters today is whether there are attempts towards the democratisation process.

We did try towards decentralisation, e g, village contribution is now collected by villages and is kept in the village as a village fund. Its utilisation is now decided by gram sabha, thereby controlling the village health workers performance. The attempts towards appropriate health education was the natural corallary but the extent to which attempts towards 'conscientisation' can breed 'health actions' is a question we have yet to answer.

It must be understood that for the goal of democratisation to be achieved the consumer should be participating. For people's participation to emerge, a felt need has to exist. The needs cannot be created. If need-based participation ensues, it has to be guided towards democratisation, the value which under-privileged section rarely visualises. It is here that the role of activist lies. The vision of democratisation is perceived by those individuals who can see beyond the immediate gains, i e, people who join the struggle through conscious committment.

As far as health work is concerned it is a moot question whether the consumers are motivated enough to actively participate. In case they are not, health work remains "for the people" and not "by the people." The experience narrated in the book describes our march towards "for the people." Though conscious of the goal "health by the people", we stumbled against the reality, that health is not a priority need of the people and hence we did not see community participation emerging.

One should not compare the strategy of work at organised sector like the Chattisgarh Mines Shramik Sangh and among unorganised rural agrarian population. Running a hospital by contributions from the beneficiaries is not new. What matters is how far the democratisation has been inculcated in health actions. It will be a nice idea if someone from Rajhara hospital shares his/her experiences of the democratisation process in health action, its feasibility and failures.

ECT and Drug Therapy: Is There an Alternative?

AR

IT is true that medicalised attitude towards psychiatric problems is a misdirected one and we have to look at psychic disorders in a holistic way (SHR II: 4). But can we totally reject the use of drugs or even electro-convulsive therapy in psychiatric illnesses? The articles tend to suggest this by denouncing psychiatry *in toto*, without giving an adequate basis for such a total rejection.

To begin with, we must distinguish schizophernia (madness) from neuroses ("queer behaviour"). It has been well-established that there is some genetic factor involved in schizophrenia. Moreover, some schizophrenics become violent either to others or to themselves; many cannot take care of their bodily functions. It is almost impossible to keep such a person in one's house without treating him/her with powerful drugs or electuroconvulsive therapy (ECT). Like any other medical therapy, ECT may have its own risks and disadvantages. If the medical establishment is hiding these, or glorifying ETC, we must oppose it. We need a better mode of treatment then ECT. The scientific basis of how and why of ECT was not at all clear when it was started and is still not clear today. But this empirically established form of treatment is on the whole quite helpful in tiding over crises, and in reducing hospitalisation and in the absence of a better alternative, cannot be rejected. Are there any alternatives better methods of treatment available? Where is the proof? Similarly, powerful psychotropic drugs also reduce hospitalisation. These methods of treatment many-a-time convert the schizophrenic into a passive, dull individual. A few who do not require long-term treatment may become almost normal but many others loose vitality in their life. But again—is there a better alternative?

Schizophrenia is not simply "deviant" behaviour. It is quite troublesome and often may be dangerous to others. If it is considered as a revolt against the society, how should society react to it? In a social political revolt, there are certain definite demands. But the schizophrenic does not have any such demands.

What is precisely wrong in conventional psychiatry is the medicalised conception of schizophrenia. ECT and drugs are not looked upon as temporary resorts in extreme conditions, but as the solution. Though there are genetic factors involved, stressful life situations, continued tensions and humiliations are often responsible for converting a genetic potential into the reality of madness. Instead of being sympathetic to the patients for the sorry state to which the society has brought them, the victims then are blamed, castigated and the role played by social-cultural conditions in creating this illness is forgotten. Unlike neuroses, a change in the family or work-environment may not bring the schizophrenic back to complete normalcy. In this regard, one is tempted to compare schizophrenia with byssinosis (a bronchitis-like condition found in cotton-mill-workers which is caused by continuous exposure to cotton-dust; once developed, it cannot be cured). Like byssinosis and many cancers, schizophrenia can be prevented. But once the damage is done, it can rarely be reversed. The real solution to schizophrenia is to create a society which would not create such stressful situations which foster schizophrenia. Even then, there may be a few people going mad, but to be sure, the incidence can be brought down considerably. But in the present circumstances, all that the medical people can do is to be sympathetic to the patient, to use drugs, and so on when essential and identify the family and society as an important cause of this malady.

In neuroses, the family and the society at large are completely responsible for a person's neurosis; there being no genetic factors involved. Early detection of "strange behaviour" and identifying the cause in the immediate interpersonal, social surrounding may help a lot. If the situation around such a person continues in the same fashion, the person may end up with serve neurosis and then the person may never revert back to complete normalcy; years of illness-creating-environment create a change which cannot be easily reverted. Drugs can only be useful to tide over a crisis. But by no means are they the real solutions.

In the absence of a holistic view of mental health and illness, and also due to vested professional or business interests of psychiatrists, and the drug-companies, psychiatry has been overused, abused. This fits well into a society where there is a culture of scienticism, compartmentalism. This overuse, misuse of psychiatry has to be opposed. We need to create a countertendency in addition, which identifies concretely pathogenic interpersonal and social practices, their economic-political basis. Such a countertendency has also to evolve and practice an alternative, healthy culture to demonstrate an alternative. The seed for socialist, healthy culture has to be sown today! But I doubt whether ECT or drug therapy for those who are already ill can be totally rejected.

SUBSCRIPTION RENEWALS

Is this your last subscribed issue? A prompt renewal from you will ensure that your copy is mailed directly from the Press. Many of our issues have sold out fast! So book your copies by renewing your subscription now!

Our new subscription rates:

For individuals—Rs. 30/- (four issues)
For institutions—Rs. 45/- (four issues)
Foreign subscriptions: US $ 20 for US, Europe and Japan
US $ 15 for all other countries (special rates for developing countries)
Life subscription: Rs. 500/-

D.D.s, cheques, IPOs to be made out to *Radical Journal of Health*, B'bay. Please write your full name and correct address legibly. And please don't forget to add Rs. 5/- on outstation cheques.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or Marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Medical Technology, Agricultural Development and Health, Health in People's Movements.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication which means that the issue on Medical Technology is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

my sin....analgin

those were the last dying gasps,
(or so it seemed then),
that were kept 'alive' with galloping agony,
that pushed my life into hopeless despair

fever juxtaposed with spasmodic chills
and that soar throat that quenched my voice
into oblivion,
was signal enough
to let loose
tiny, horrendous microbes,
in tens of thousands, millions and billions,
to pounce on my flesh,
in an effort to strip me to my skeleton.

the healing messiahs,
gathered around me
(in a state of helplessness)
pumped desparately blood into me,
to replenish the granulocytes,
that had vanished from my blood,
thanks to the pain-killer,
which i was prescribed.

i survived somehow.
they said i was lucky.
"it's a miracle,
50 percent don't see through."

"pain-killer ? driving me to the height of agony ?
plunging me into misery ? dragging me to death ?
why make such a monster ? "i cried
with a voice that had barely returned.
and the messiahs said,
there were 'profits' in making this monster

"profits"?" i was puzzled.
"profits" they said,
"for companies which manufacture it,"
"profits for the governments which allow it,"
"profits for the messiahs who prescribe it,"

"but what of me" i said,
"i was pushed into the doors of death."
" oh !" they said,
"you are just one that gets into such a mess,
after every hundred thousand."

i wished i was amongst
those 50 percent who did not see through,
for this callousness
was more agonising than the disease.

"but what was my crime,...what was my sin."
they laughed cynically... "you ingested analgin."

MEDICAL OFFICERS—THE 'NEW MIDDLE CLASS'?

The views expressed in the signed articles do not necessarily reflect the views of the editors.

State in Health Care

THE Indian tradition of state intervention in health care is quite old. During the reign of Asoka in 3rd century BC, besides other social welfare measures, the state established medical centres for man and animals, undertook planting of medicinal herbs and trees, and supply of potable water through wells along the highways. Similar medical centres were claimed to have been established in the neighbouring countries at Asoka's instance (Thapar, 1973). In modern times, a major role of the state in health care service has universally been recognised and accepted. Politics of each country determines the nature of intervention and quantum of contribution by the state. For instance, in the socialist countries the state has assumed the entire responsibility; UK operates the unique National Health Service; in Canada and New Zealand, the state bears almost the entire expenditure; in many European countries the allocation by the state is ever increasing; and in the third world a similar feature is discernible. In India pressure on the government to spend more on health care is quite strong. The state's role varies ranging from the direct and absolute state administration to indirect and partial intervention.

In India, the situation is somewhat peculiar. The state has undertaken the entire responsibility of health care of the personnel of the army, parliament and the railways; partial responsibility of the other employees of the government and public undertakings. and a dubious responsibility of the mass of people. Historically, modern health service owes its beginning to the British presence. Although the first legislation in this respect, the Quarantine Act, had been introduced in 1825, real concern for a state operated health service appeared after the 'Indian Mutiny' or 1857 in the context of the over-riding political necessity to safeguard the health of the troops and the European civilians. All health intervention were geared to achieve this objective. However, endemic and often epidemic prevalence of communicable diseases as well as political compulsions put sustained pressure upon and eventually forced the government to do something for the native civil population which relied largely on traditional indigenous system (see SHR, Vol II, No 3). Montague-Chelmsford Constitutional Reforms of 1919 and later the Government of India Act, 1935 decentralised the responsibilities which devolved almost entirely on the provincial and local authorities. This constitutional framework and the policy outlined in the report of the Health Survey and Development Committee (1946) had been the basis of policy guidelines for the national governments.

Article 47 of the Indian Constitution clearly avows, under the Directive Principles of state Policy, the state's responsibility to raise, "the level of nutrition and the standard of living of its people and the improvement of public health as among its primary duties". Here, the 'state' actually means the seat of the Union Government. But the VII Schedule allocates almost all responsibilities to the provincial governments, e g, public health, sanitation, hospitals and dispensaries, drugs, family planning and population control, medical education, medical profession, prevention of the extension of communicable diseases from one state to another and vital statistics have been placed under the Concurrent list, while the Union list mentions only Port Quarantine, and determination of standard in 'scientific and technical institutions' meaning perhaps also medical institutions. In actual practice, however, the Union Government deals with international health relations, promotion and conduction of medical research, regulation of production, quality control and trade of drugs, regulation of standard of medical education, vital statistics, and medical care of employees. National disease control/eradication programmes, family planning, MCH, drinking water supply, etc, are financed by the Union Government and operated through provincial health organisations. Moreover, there are several other spheres where the Union Government makes some contributions, e g, medical education, health education, health information, dissemination, drug production, development and promotion of other systems of medicine, rehabilitative medicine, paramedical training, etc. Provincial Governments, on the other hand, not only enjoy almost absolute autonomy in health care operations both at the policy and implementation levels, but are supposed to exclusively provide for medical care and public health services. Juridically therefore, it may be argued that the Union Government contirbutes more than its share in health care services.

But then one fundamental aspect is missing in such analysis. Health care includes, as is now widely known, adequate nutrition, safe water and sanitation, healthy environment, education, employment, etc. Solution of these problems is necessarily dependant on the economic system and political programme, i e, the conduct of the Union Government. It may therefore be held that the basic determinants of health necessary for the protection, maintenance and improvement of health of the people are to be provided by the Union Government and the Provincial Governments are responsible for the provision of universal medical care which is no less an important determinant, if not the most.

Till now the health of a community of people or that of country is measured and appraised by certain parameters, e g, infant mortality rate, death rate, expectation of life at birth, sanitation, per capita consumption of food and safe water, etc. In the context of such parameters, India has made steady progress in the post-independence period. But in the context of desirable goals and international standards the Union Government admitted that such progress brought little benefit to the Indian masses and the health situation of the country was still precarious and alarming (GOI 1982).

In the background of this reality the Government of India endorsed the WHO target of "Health For All By The Year 2000 AD" which called for the following intermediate goals:

1985—Providing right king of food for all;

1986—Providing essential drugs for all;

1990—(a) providing adequate basic sanitation for all;

(b) providing adequate supply of drinking water for all;

(c) immunisation of children against six common

diseases, *viz*, measles, whooping cough, tetanus, diphtheria, polio and TB.

Needless to say, the targets for 1985 and 1986 remain unrealised. But the point is—'food for all' has already been a declared goal of the Indian State since the adoption of the constitution. A period of three and half decades has made it obvious that the Indian State has neither the means nor the political will to achieve that goal. Hence, the endorsement of the targets set up by the WHO appears to be either a mere formality or an exercise in duplicity.

Turning to the matter of medical intervention which is dominated almost exclusively by the provincial government, we need to face certain facts:

(1) State medicare is practically free to all without discrimination from millionaire to pauper; though in respect of finance and administration there are provincial boundaries services are available to all transcending such boundaries; those who enjoy guaranteed medicare through certain agencies are also welcome to the state's free medicare; and even foreigners are not put to any restraint in obtaining free medicare from the state institutions.

(2) There exists a strong and evergrowing private sector of medicare consisting of hospitals, nursing homes, clinics, diagnostic set-ups and dispensaries, which constitute ¾th of the medicare field.

(3) Overall superiority in specialisation, sophistication, modernisation and excellence is still attributed to the state sector for various reasons.

(4) State medicare institutions are disproportionately concentrated in the urban areas, and the rural institutions, meant ostensibly for comprehensive health care, have mostly turned into curative agencies.

Conceptually therefore, state medicare is delivered more on the principle of charity and not obligation or welfare. It is not then surprising that the resulting situation is disorganisation, deterioration in quality, unscientific practice, corruption, chaos and frequent break-down of law and order. In the ensuing 'free for all' for the cost-free medicare, the weaker sections are deprived of health care.

Medicare is provided to the industrial workers through the unique Employees State Insurance (Medical Benefit) Scheme, financed jointly by the workers and the employers, regulated by the joint body of employees, employers, Union and Provincial Governments and medical profession, and operated by the provincial governments. Services are rendered for sickness, maternity and employment injury. This scheme could be viewed as a forerunner of national health service but there is a big difference in the matter of financing compared to the similar schemes in other countries.

Financing of health services in India presents an interesting story. While the share of the allocation on health care has steadily been reduced in the Union budget in the successive 5-Year Plans, that on family planning increased with a sharp upward jump in the 4th Plan. In terms of GNP it has not exceeded 0.5 per cent compared to 5-10 per cent in several developed countries—(GOI, 1975, 78, 79, 80-81). In terms of the state's share in the total health expenditure of the country, India (24 per cent) is way behind not only the developed countries but even Sri Lanka (50 per cent) (Roemer, 1984).

Steady increase of state intervention in health care is a distinct feature of capitalist society and it is explained in various ways. It is argued that state health care expenditure is a form of social wage to the labouring class and it serves the need of capital for the steady flow and reproduction of labour power and to maintain/increase productivity. This view is also discounted by the argument that historically the technological changes or a relative scarcity of labour have been found to be more effective than higher rates of medical expenditure in obtaining increased productivity (Doyal an Pennel, 1979). While there is positive evidence that public health legislation of the 1840s in UK resulted in improving the productivity of labour, in India, fluctuating state expenditure on health does not appear to bear any corresponding relationship with availability of labour in the market. There is broad agreement among the marxist commentators that the ruling class meets the social needs of capital through the state invervention in health care or for that matter through all social welfare measures. It provides a benevolent image for the state maintaining support for the existing system, and developing the dependency on the state. It legitimises bourgeois ideological underpinnings. On the other hand, it is asserted that increasing state intervention is the product of the social demands of labour, achieved through class struggle. Fluctuation of the magnitude of intervention generally corresponds with the differing intensity of class struggle. Then again it is argued that there is actually no contradiction between the two explanations and there is no single-factor explanation of social policy. Social demands of labour seek increase in social wages and public ownership of means of production. Social needs of capital are served by employment absorption of surplus population and provision of social services pre-empting conflict and unrest from unemployment, uncertainty and physical distress. The nature and number of the combination of factors depend on the historical situation, level of development of productive forces and relations of production and the level of class struggle. "There is no clear-cut dichotomy between the social needs of capital and social demands of labour. Any given policy can serve both. Indeed, social policies that serve the interests of the working class can be subsequently adapted to benefit the interests of the dominant class... Indeed history shows that concessions won by labour in the class struggle become, in the absence of further struggle, modified to serve the interests of the capitalist class" (Navarro, 1976).

What role of the state do we then envisage for an egalitarian health system? The distorted nature of medicine under capitalism and the discriminatory delivery of health care have produced diverse reactions. Total state control or nationalised health care, integrated health care meaning integration of other relevent state services with health service, decentralised health care calling for peoples participation and sharing of power in planning and administration, debureaucratisation, i e, replacement of generalists' control by professionals, people's health in people's hands signifying vague assertion of self care and self-contained community management—are some of the prescriptions. The reactions seem to ignore the determinist nature of state intervention. With the growing magnitude of socialisation of the production process, the state inevitably assumes more and more

(Continued on page 108)

Political Economy of State Health Financing

ravi duggal

In a capitalist state the government is a functionary of capitalism—its role is to protect and strengthen it. Thus the state's behaviour even with regard to the health sector programmes, is a function of private capital.

The health sector started with a very low priority and has gradually gained an increased share of the state's expenditure, the growth rate of health and family planning expenditures has been much greater than both the growth of government expenditure and the gross domestic product. But this does not reflect an improvement in health care services provided by the state. Why this is so and what role state financing of health care has played is examined in this article with specific reference to two states, Gujarat and Maharashtra.

THE health sector is popularly perceived as being part of the social services sector. The corollary to this being that it automatically becomes largely a responsibility of the state. This perception is common even among the most advanced capitalist states.

Health and education (besides unemployment insurance in a few countries) are the 'classical' sectors within the umbrella of state welfare. Over the years, all over the world, these two sectors have increasingly been supported through public finance for various reasons. The most important being the predominance of the view that they are a social service and therefore, not in the direct interest of private capital. Nevertheless, they being an important social need had to be met, and therefore public finance became the provider increasingly.

The historical consequence of this development has been a greater role for the state in meeting the needs of the people. Since state finances come largely from taxes the household and corporate sectors have gradually begun to feel the brunt of letting the state take care of the social sector. Given the nature of the capitalist state there comes a point beyond which taxing private capital becomes a threat to capitalism itself. Thus emerges a "fiscal crisis of the state" and there is talk of cuts in welfare and social expenditures. The pressures of capitalism in its pursuit of surplus appropriation is responsible for this.

Advanced capitalism, especially monopoly capital, and the state have a love-hate relationship. Love, because the survival of capitalism is dependent on state protection and support, and hate because increased state expenditures mean enhanced taxes and public debt that may terminate in a fiscal crisis, or worse a social one.

Of late this realisation has hit capitalism, which sees the dangers inherent in an increased burden of state welfarism. The result is increased "corporate welfare". This is happening in the USA in a large way and the health sector is the best illustration. Expansion of private health care (especially corporate) in the last three or four years in the USA has been phenomenal. What is more is that it has also been realised that the social sector, especially health, can be a highly profitable one. This is largely facilitated by modern technological advances in health care. For instance in the USA between 1980 and 1984 corporate revenues in health care grew from $ 25 billion to $ 118 billion, along with increased monopolisation through mergers and takeovers (in spite of anti-trust suits). And in the same period, of the 37 largest health and welfare corporations only two lost money, whereas 13 more than doubled their revenues and 11 more than quadrupled their revenues (Stoesz, 1986).

This trend is true for most advanced capitalist countries and is fast emerging in backward capitalist countries too. In the last two years in India over Rs 200 crore have been spent by the corporate sector in setting up 60 diagnostic centres (CT scan etc.) all over the country, of which 46 were set up by the United Group alone (Business India, Dec 29, 1986).

This, however, does not mean that the state health care sector is on the decline. Historically the state health sector as well as other state welfare and development programmes have served the needs of private capital (see Galper, 1975). We will return to this later.

The state financed health care sector in India is 'patronised' by only about one-third of the country's population, of this roughly 80 per cent being urban. That is two-thirds of India's population utilise private services for health care; and the state's health services are concentrated disproportionately in urban/industrial areas. It may also be noted that municipal health services, railway, defence and mining health services, as also those services provided by public sector undertakings are not accounted for under 'state health expenditure'.

Health is a state (provincial) subject and therefore the responsibility of providing health care vests with the concerned state. However, the union government does make a substantial contribution to the states through grants and centrally sponsored health programmes. Besides, policy making and planning for the health sector has largely been determined by the centre.

The state health sector in India incorporates three components (a) Medical Services including CGHS and ESIS, (b) Public health (including water supply and sanitation) and (c) Family Planning (including MCH). Family Planning is almost entirely a centrally funded programme (it falls under the concurrent list). In this paper we will look at the health sector as including only the first two components, treating family planning independently.

The major sources of data for state spending on health care are (a) The Combined Finance and Revenue Accounts (CFRA) of the Union and State governments compiled by the Comptroller and Auditor General of India, (b) Summarised Accounts in the Indian

Economic Statistics: Public Finance, compiled by the Department of Economic Affairs of the Ministry of Finance, and (c) The Performance Budgets of health ministries of the respective states.

In the CFRA data is available state-wise but the disaggregation is of little use because the categories used are administrative ones like 'establishment', 'direction', 'grants' etc. However, the state's Performance Budgets give programmewise expenditures but these documents are not easily available; and if available are too voluminous for a time-series analysis. Therefore, in this paper national aggregate figures will be used for an overall analysis, and a case study of programme based analysis will be done for Maharashtra and Gujarat states.

State Financing of Health in India

The Indian constitution in its 'Directive Principles of State Policy' has vested the state with responsibility for providing free health care services to all citizens.

Where does the state stand on this issue?

Analysis of finances of the state reveals that the health sector started with a very low priority and has gradually gained an increased share of the state's expenditure, stabilising between four and five per cent of the government's total expenditure. Similarly state expenditure on health care has shown marginal increases over the years with regard to proportion of the Gross Domestic Product. Table 1 'A' and 'B' presents data in this regard by various plan periods.

The most interesting finding that emerges from this data is that the growth rate of both health and family planning expenditures have been much greater than both the growth of government expenditure and the gross domestic product. Further, as per the estimates of 'National Accounts' we see that the gap between state health expenditure and private medical expenditure is narrowing. These facts are indicative of high investment in the state health sector, but, unfortunately, the results of health programmes do not corroborate this. Why is this so?

Firstly, the level of investment and expenditure in the state health sector, though experiencing a growth rate higher than total government expenditure, is at a fairly low level. For the year 1984-85 the allocated expenditure for the entire state health sector was Rs 3,287.8 crore, working out to a meagre Rs 43.84 per capita per annum (1.54 per cent GDP and 5 per cent of government expenditure). This includes expenditure on medical services and national disease programmes, public health and PHC, water supply and sanitation, CGHS, ESIS, MCH, family planning, medical education and research, health bureaucracy, construction of new health centres and hospitals. At today's market prices providing the above services adequately to the entire population free of cost requires much more expenditure than is earmarked presently.

Secondly, a large proportion of health expenditure in the III, V and VI Plan periods, when the growth rate of health expenditure had been the highest, went into infrastructure development i e, water supply schemes and construction of health centres. In fac more than one-half of the medical and public health expenditure since the III Plan period is spent on water supply and sanitation. The plan holiday period and IV Plan, when capital expenditure was very little, show low growth rate in health expenditure. And, in spite of this the health infrastructure remains poor. Even today the government is nowhere near the level of infrastructure and facilities recommended by the Bhore Committee in 1946.

Thirdly, between 70 and 80 per cent of the investment and expenditure in the state health sector goes to the 30 per cent population in urban areas. This mismatch (of rural-urban disparity) by the state is in spite of the fact that urban areas also have access to other public and quasi-public health care facilities such as municipal and other local body hospitals and dispensaries, municipal protected water supply and sanitation, municipal funded medical education, ESIS and CGHS for industrial and government workers and so on. For instance in 1983 in Maharashtra, of the total 478 state-owned (central and state government) hospitals and dispensaries 432 (90 per cent) were in urban areas and of all the state owned beds 97 per cent were in urban areas. And of all the beds in Maharashtra (public and private) 30 per cent were in Bombay city alone (SBHI, 1983).

Fourthly, leaving aside the preventive and promotive services, the curative services provided by the state, especially in the rural areas, are grossly inadequate. That curative services are the priority demand of the people vis-a-vis health is evident from various studies that have shown that even in rural areas the private medical practitioner provides services for between two-thirds and three-fourths of illness episodes in the population.

Following from the above, the private medical sector becomes a strong adversary to the state sector because the former is totally curative-oriented, because it is 'efficient' and non-bureaucratic, because it is 'effective' and most importantly because it is easily accessible

when needed.

And finally, the credibility of the state's rural health services is very low. This is largely due to its obsession with family planning targets. Over 60 per cent of the PHC staff's time is spent on family planning work.

Thus, the high growth rate of health expenditure is a deceptive feature, because disaggregated it reveals the unhealthy direction of growth. In the following paragraphs the data in each column in Table I is analysed in detail.

Medical and Public Health

In the health sector the Britishers did not leave any significant legacy of an infrastructure. Therefore, a beginning from scratch had to be made after Independence. What was left by the British was an exhaustive Plan called the Bhore Committee Report, a small network of civil hospitals, a few medical colleges in premier cities and a network of military and railway hospitals. No rural health infrastructure of any significance existed at the time of Independence. The expenditure by the British state was meagre (see Appendix 1).

However, even after Independence the Indian state did not deem the health sector to be a priority. In the First Plan period the state spent an average of Rs 39.40 crore per year which was only 2.2 per cent of total government expenditure and only 0.39 per cent of the GDP; much less than what the British government had been spending. At the end of the First Plan, besides 725 PHCs there were 3307 hospitals, and 7100 dispensaries in India, the majority of hospitals belonging to the state (breakup of ownership for this period is not available).

In the Second Plan period the expenditure on medical and public health more than doubled and this pattern continued in each subsequent plan, except during the 'plan holiday' and the IV Plan when growth rate of health expenditure showed a drastic decline. Health facilities too increased but they remained heavily skewed in favour of urban areas. With the launching of the Minimum Needs Program, from the IV Plan onwards rural health infrastructure began to receive some significant attention.

Table 2 lists health care facilities in India. It is evident from this table that the health infrastructure is very poor even today, especially so in rural areas. The best indicator of health care facilities is the number of hospital beds available to the population. The earliest year for which this break-up is available is 1956 when 25 per cent of all hospital beds (government, local body and private) were located in rural areas that had 80 per cent of the country's population. This declined to 13.7 per cent in 1974, clearly indicating that the rural areas had been neglected grossly where investment in the health sector was concerned. Even where PHCs are concerned it is clear that the number of PHCs added over the years has not been adequate for the rural population as between 1966 and 1984 the PHC: Population ratio has remained constant at one PHC

3. Planning Commission, Seventh Five Year Plan 1985-90, GOI, 1985.

for 80,000 population. This stability (sic) is also true of the hospital/population ratio.

However, the point that emerges most significantly from Table 2 is the fact that since mid-seventies there has been a sharp rise in the proportion of health facilities in the private sector as compared to the state sector. Thus, in 1974 the private sector accounted for only 16 per cent of hospitals in the country but within a decade the private sector's share of hospitals rose 2.83 times to 45.3 per cent, and that of the state sector declined from 62.6 per cent in 1974 to 49.3 per cent in 1984. The change in the proportion of hospital beds in either sector was not as sharp.

Therefore, it becomes very clear that both the "high" growth rate of the state health sector and the narrowing gap between state and private health sector expenditures is only an illusion created by aggregated data.

Family Planning

Expenditure on family planning (now including MCH, CHG scheme and the EPI program) is almost entirely financed by the central government through 'plan' funds. Allocations to FP have increased at a phenomenal rate in each plan period. Between the First and the Sixth Plan periods the *allocation* increased from Rs 0.65 crore to Rs 1010 crore i.e. 1554 times, and more astoundingly FP *expenditure* increased from Rs 0.15 crore to Rs 1626 crore or 10840 times, whereas total plan expenditures in the same period increased only 50-fold and health expenditure (plan and non-plan) only 57 times. Computing this growth rate may sound unfair because FP started with a very insignificant allocation in the First Plan period but the fact remains that the growth of family planning expenditure has been at the cost of expenditure on health care services. In the VII plan for the first time plan allocations (revised) to FP are higher than that for health.

Further, in each plan period we see a decline in growth rate of family planning expenditure and the growth has been the lowest, ironically, in the Emergency period (Vth Plan). Therefore, this computation too is unfair. This is the illusion that aggregate statistics project!.

Notwithstanding this, the growth of family planning expenditure remains higher than that of health expenditure. And further, it may be noted that at the implementation level a large proportion of resources and personnel-time allocated to health is used for family planning work because the latter ranks as priority number one in state policy making. (For details on Family Planning financing see Duggal, 1986).

Private Medical Expenditure

It has already been pointed out earlier that over two-

* Plan expenditure was Rs 3768 million. Since the non-plan figure was not available the author has estimated it to be half each.

thirds of health care services utilisation is in the private sector and the remaining is divided between the state sector and other public and quasi-public institutions.

In Table 1 we see that the growth of private medical expenditure has been much slower than the state health sector. As a result the gap between the two has narrowed down to almost unity during the VI plan period. This is contradictory to two facts indicated in earlier sections. Firstly, that between two-thirds and three-fourths of health care utilisation is in the private sector. And second, that the growth rate of the private health sector after mid-seventies has been very high (see Table 2).

Therefore, this data on private medical expenditure computed by the CSO in 'National Accounts Statistics' is highly questionable. Studies carried out by the Foundation for Research in Community Health indicates much higher estimates of private medical expenditure. For the year 1983-84 it has been estimated that the total health expenditure in India was Rs 16,386.41 crore or 8.33 per cent of the GDP. Out of this only 11.7 per cent was spent by the state, 60.4 per cent was spent by private households, 22.7 per cent by the corporate sector (private and public) for its employees and 5.2 per cent by local bodies. Also, with regard to private household health expenditure a gross rural-urban disparity is seen—in rural areas an astonishing 94 per cent of health expenditure was borne privately by households whereas in urban areas this burden was only 35 per cent of their health expenditure (*FRCH*, 1981). This is mainly because urban areas have access to better state and other public (such as municipal) health care facilities as also to employer or insurance sponsored health care programmes. Expenditure of selected agencies is presented in Table 3. *Ratios*: A few selected ratios have been computed from Table I and are presented in Table I 'B'. The data in this Table speaks for itself and it has also been referred to in earlier sections. Therefore, we leave it at that.

State Health Expenditure on Health Programmes

As mentioned earlier disaggregated data for state health expenditure for the nation is not available on a programme-wise basis, except for plan expenditure. Therefore, we will look at the state (provincial) level to get a detailed breakdown.

Where plan expenditure is concerned consolidated data is available for eight categories. Table 4 presents this data. It is clear from this table that water supply and sanitation leads as expenditure number one grossing between 30 per cent and 50 per cent of the health sector Plan—it has grown in each plan period taking a larger proportion each time.

Family planning on the other hand started by being the lowest funded programme in the first plan (0.3 per cent) to gaining second position (27.56 per cent) after water supply, by the V Five Year Plan. As a consequence all the other programmes have suffered and have had a smaller share in each subsequent health plan since family planning took over the second position in the IV Plan. Thus the priority of the state in the health sector is fairly clear—strongly in favour of FP at the cost of other crucial health programmes.

Unfortunately such a breakup is not available for state health expenditure outside the plan. But at the state-level detailed disaggregation is available. Table 5 gives a breakup of various health programmes for Maharashtra and Gujarat during the VI Plan period. Water supply and sewerage is the largest single category of expenditure in each sate—as a percentage it is as high as 47.45 per cent in Maharashtra and only 22. 6 per cent in Gujarat.

If one leaves aside water supply, then medical relief accounts for the largest category of expenditure in both Maharashtra and Gujarat. This is followed by family planning, control of communicable diseases and ESIS. The other programmes follow a different sequence of priority in each state. The per capita per annum state health expenditure (inclusive of water supply) for Maharashtra and Gujarat works out to Rs 48 and Rs 35 respectively.

Thus the priority and pattern of expenditure for various health programmes is not very different from that we have seen for 'plan expenditure' for the country. Of course, it must be noted that Maharashtra and to some extent Gujarat are the better performing states vis-a-vis the health sector.

Role of State Health Sector

In the foregoing analysis we have seen that within the health sector two programmes stand out prominently—water supply and sanitation and family planning. Ironically both these programmes are not perceived by the people as health programmes. For the general population health care is synonymous with curative services and this does not have a very high priority with the state.

Why do water supply and sanitation and family planning feature as high priority programmes? Water supply itself has high priority with people, may be even greater than medical services, but this is not the reason why it is so heavily funded.

The role played by imperialist agencies is very crucial in understanding this. If one lays threadbare the development programme expenditures of the state it is clear that those programmes which receive financial support through various imperialist agencies, such as bilateral (USAID, ODA, DANIDA, etc), multilateral (World Bank, WHO, etc) or private (Ford, Rockefeller, Population Council, etc), get into the state's priority list. The Indian state, being part of the world capitalist system (though backward), is greatly influenced by it in its policy and programme making. Thus water supply and family planning and a few selected communicable diseases (malaria, earlier small pox, now measles and even AIDS) get top billing in the state's resource allocation. If one goes through the CFRA or RBI Finance Reports of any year and looks up the section on international debt the correlation between plan

priorities and public finances and foreign debt becomes clear. Power projects, transport and communication, industrial infrastructure, mining projects, irrigation projects, water supply schemes and population control projects are the major areas of international debt financing. These areas also happen to be the ones that take the cream of our plan public finances. These are the very areas in which India lacks technological skills and has to rely on multinational corporations. This is too good to be a mere coincidence. If one were to list all the significant water supply schemes and the population control projects in India there would not be a single project that did not receive foreign finances (see RBI, 1984).

This nexus does not exist only at the international level but also within the country between the state and private capital. In a capitalist state the government (the functional form of state) is a functionary of capitalism—its role is to protect and strengthen it. Thus the state's behaviour, even with regard to the health sector programmes, is a function of private capital. The state's financing patterns of various health sector programmes are primarily the fulfilment of the needs of private capital. At the time of Independence the Indian state lacked any significant health structure. The Indian bourgeoisie was not prepared to enter this 'social sector' and therefore it allowed the state to develop this sector. And today when a bare minimum of health infrastructure has been developed and is functional the bourgeoisie, following the footsteps of its western allies, has stepped in a large way in the health sector. In fact, in the next three or four years large financial investments by the corporate sector in health care have been planned.

Further the curative health care sector, which has priority with the people and which forms the *raison d'etre* of the entire pharmaceutical and medical equipment industry (overwhelmingly controlled by the private sector, especially MNCs), has received a very lukewarm attention from the state. This is because the entire private practice of medicine thrives on curative services. It is the life-line of the private health sector. Private practice of medicine, which looks after three-fourths of the population falling ill, has never been controlled by the state. It has been given a completely free hand to operate and amass surplus.

Most of the doctors who get into private practice are trained at public institutions run entirely through public finances. Thus the state is directly responsible for creating an exploitative private health sector. The state is also a very large buyer of drugs from the private drug companies. The state provides tax concessions for running private hospitals under the grab of 'public trusts' that are referred to as 'voluntary hospitals'. (According to the Directory of Hospitals in India Maharashtra state does not have a single private hospital. Jaslok, Breach Candy, etc are listed as 'voluntary' hospitals!).

Thus we may conclude that the state's health expenditure which has been gradually increasing over the years, grows in an unhealthy direction, is urban-biased, anti-poor and above all is invested for the health of private capital.

State in Medical Care

sujit k. das

The nature of state intervention in medicare has been determined by two factors the demand of the people on the one hand, and the ruling classes' urge to acquire legitimacy and credibility on the other. Often enough policies which have been a consequence of the pressures brought to bear by the working class, have subsequently adapted to benefit the interest of the dominant class effective medical care to the poor, can never, the article contends, be provide by a state geared to the interests of capital accumulation.

MODERN societies, without exception, view certain basic health care services as commodities to which every member of the society should be gauranteed access, regardless of their ability to pay. This general proposition seems widely shared among nations, whatever their cultural and political complexions; vastly different approaches, however, have been adopted for acting on that precept" (Reinhardt, 1982).

Reinhardt's statement reflects a somewhat universal value; but, besides approaches, the understanding and interpretations of the general proposition he mentions also differ widely. Though it has long been established that 'basic health care' includes food-cloth-shelter-safe water-sanitation, etc, as popularly understood in India it actually means medical care, i e, medical intervention to prevent and treat diseases. That is why the Indian state maintains a large number of institutions where a citizen, dying from some disease, may claim free life-saving medical aid. There is no state agency which provides free food to a citizen dying from hunger or for that matter clothing, shelter, etc, to the similarly deprived. Neither is there any demand on the state from any quartor to arrange for such provisions. In fact, conceptually it is yet to be accepted that the basic elements of health care should be provided free to the pauperised people; to each according to his ability—is the motto; one should earn his living—is the precept. Emergency situations, e g, disasters like floods, earthquakes, accidents, etc, of course, make exceptions. In contrast, universal free medical care by the state is not only welcome but such provision is actually there and more is being demanded.

The endeavour to provide medical care for its members by human society is as old as any other social activity. state, religious institutions, voluntary collective efforts—all have played their part. Modern societies, enriched by modern scientific knowledge, have turned their attention to basic health care with, as Reinhardt says, vastly different approaches. In the socialist countries, state intervention is almost comprehensive in all aspects though the citizens contribute in varying proportions to its financing. In the developed capitalist countries state intervention in the matter of safe water supply, education and sanitation is quite significant and, though food-clothing-shelter remains as yet an individual responsibility, various social security schemes help the pauperised citizens and guard against death from deprivation. As regards medical care, approaches are different. In the US there is no direct state intervention and the semblance of a free market is sought to be preserved, but with the introduction of medicare (for aged) and medicaid (for poor) programmes and financial support to other agencies, the financial contribution of the state has, steadily in the last two decades, come to bear the largest share in the national health care expenditure. United Kingdom's National Health Service is somewhat unique and rather incomparable among the capitalist countries as it is run entirely with state revenue. Other countries heavily depend on different kinds of insurance systems with heavy state and employer contributions. In Canada medical care is almost totally state care.

Among the developing and under-developed countries, the trend is similar. Pressure on the state to provide for more and more health care is put from all corners—deprived classes, liberal section, political forces and international community—albeit from different motives. Accordingly state health care is expanding more rapidly than private sector health care. The Indian scene may be reviewed in two categories—non-medical health care and medical care.

The debate in the wake of WHO's call 'Health For All' has brought about a change in the concept of non-medical health care. It not only includes food-clothing-shelter-safe water-sanitation-pollution-free environment, etc, but is also held to be dependent on education, economic security or effective employment, women's equality, social justice, political control over economy, etc. For all these factors, the supreme role of the economy is indisputable. The market economy does not care for the achievement of all these health determinants for the broad masses. Clearly, the private sector of the economy cannot be induced to work for equitable distribution of non-medical health care, nor can such health care be achieved through individual efforts. Its realisation depends entirely on the political direction of state policy and its effective implementation. In other words, non-medical health care for the masses depends entirely on state intervention for the development of new economic relations conducive to equitable distribution.

Why State Medical Care?

State intervention in medical care depends not so much on the economic structure of the social formation; all societies appear to agree on the state's increasing role in providing universal medical care. The extent and magnitude of state intervention depend primarily on political commitment and then on the level of development of the state as an institution and on the degree of its dominance over social activities. In India,

the operation of preventive medical intervention, e g, national disease control and eradication programme, routine immunisation, etc, is almost exclusively in the hands of the state. Free curative services operated by the state effectively reach only a few selected target groups, e g, government employees, including the armed forces, organised labour force (ESI), and the socially powerful minority in both urban and rural areas. The rest of the population depends upon various kinds of private and corporate services. All concerned people agree that the services are inadequate and effective curative services do not reach the largest section of the people in need. A variety of prescriptions have been offered as remedial measures and these should be considered in their political and economic dimensions.

It is often argued that liberal philanthropic welfare has given way to capitalist welfare measures, e g, medical care which is intended to contribute towards maintaining reproduction of labour; state medical care, like education, is actually a part of the social wage of the labouring class. This argument appears to be relevant in the context of an advanced capitalist economy where the role of skilled and highly skilled labour is significant and capital's stake in developing that kind of labour is high enough to justify large state allocations to medical care in order to maintain the health of the labour force. In the drive for accelerated industrialisation in USSR and China, state policy accorded priority to maintaining the health of the labouring force by organising medical clinics in each factory complex (Deacon, 1984; Wilenski, 1979). But this argument is not sufficient to explain the Indian situation. Labour in Indian industry and agriculture is mostly low-skilled and unskilled and the reserve force is so abundant that its continuing health and quality cause the least worry to the capitalists. There is as yet no evidence to suggest a linear co-relation between productivity and improvement of the health status of the people. Even in the case of the ESI, the apathy and neglect of the state as well as of the employers indicate that they are more interested in something other than the protection of the workers' health. On the other hand, the argument that the entire state medical care service is entended to earn legitimacy for the ruling classes and the existing social order and to secure credibility for the state as the benevolent friend of the poor appears to be more plausible. It will be evident if the real state of affairs prevailing in the operation of the state health service is reviewed.

State authorities never tire of proclaiming that the state service is free and is meant for the poor. Actually, both the principle and practice are otherwise. In principle—legal, constitutional and otherwise—state medicare is not meant for the poor alone. By policy the access is universal. Both the millionaire and pauper have equal rights to claim free state service. Not only that, the population groups who enjoy exclusive access to reserved medicare schemes, e g, CGHS, ESI, railway, armed forces, public undertakings, big industries, etc, also receive free treatment from state hospitals without restriction. Even foreigners are freely entertained as a routine. What happens really is that the larger portion of effective state medicare is cornered by the socially-economically-politically powerful sections who, in addition, are exclusive recipients of other medicare projects not accessible to the poor. That the real objectives of state policy are compatible with this situation is evident from the fact that state medicare infrastructure is concentrated in the urban areas; that provision of high cost medical technology, e g, C T Scanner, Echodiagnostics, cancer-therapy, intensive care, surgical super-specialities, etc, which have little relevance to the major medical needs of the poor (TB, leprosy, enteric disease, bacterial and parasitic infections, etc), is rapidly increasing; and that the state frequently spends large amounts for high cost treatment of dubious outcome for the VIPs. An example: state medicare in West Bengal is fairly well developed compared to other provinces. But even after the devastating experience of the enteric disease epidemic in 1984, the government is unable to provide for cheap oral rehydration salt packages to the chronically afflicted population on account of stringency of funds which does not impose any constraint, however, on the expansion of high cost technology proceeding as per schedule in the metropolitan hospitals frequented by affluent clientele. Secondly, state service is far from free for the poor. Supply of the needed essential drugs is grossly inadequate and people have to purchase these as a routine. In the urban and semi-urban hospitals it is now customary to engage at the patient's own cost an additional care-taker in order to obtain minimum necessary caring services. The practice of some form of payment as premium to the doctor or hospital worker for the privilege of admission in a free bed is still rampant in most of the provinces. Quite frequently such premiums ae obligatory for investigative, surgical and similar services. It should however be kept in mind that even with the premium, state service, on the whole, is much cheaper than the market product both for the poor and the affluent.

Medical Care vs Non-Medical Care

Official versions of state policy, expert commentators and the WHO strategy for Health For All—all in quest of better health for the people—emphasise non-medical health care and preventive intervention and underplay medical care. As a long-term strategic approach this cannot be disputed. But a good deal of ambivalence and many contradictions appear in the field of practice. The strategic approach takes into consideration only the conventional measurable indices of health, e g, mortality, morbidity, disability, water supply, sanitation, etc, on the one hand and the proportion of doctors, paramedics, beds, drug consumption, etc, per unit of population on the other, in determining the efficacy of health care service. But medical care serves a prime need which cannot be quantified or statistically measured

Healers have been venerated and honoured since the infancy of human society for the vital function they perform both at the individual and social levels; they respond to human distress. Most of minor illnesses treat themselves; people learn to tackle a good number of everyday physical ailments themselves; when people seek a healer it is a response to more than the mere physical illness but includes added factors of apprehension, fear and helplessness which compound the distress. The healer propounds an explanation of the causation of ailment (however weird), prognosticates, takes charge of the battle, relieves the patients of their helplessness, applies his technology (however primitive and absurdly ritualistic) of diagnosis and treatment and emerges triumphant when the self-healing ailment heals itself. The entire episode restores confidence and balance to the sufferer and his kinfolk, enabling them to again face the adverse world with renewed courage—the unknown enemy is now known and conquered and the healer, the weapon to tackle the enemy, is there. Even when the healer fails, he allays distress, offers comfort and finally legitimises death, the most fearful enemy, by performing rituals intended to ensure a comfortable after-life for the dead. This is one of the most vital psycho-social functions for mankind to adjust to environmental adversity in the struggle for survival and progress. Biologically potent therapy came much later, only recently. In fact, as late as in 1980, Oliver Wendell Holmes wrote that, except for opium and wine, "if the whole *materia medica*, as now used, could be sunk to the bottom of the sea, it would be all the better for mankind—and all the worse for the fishes". Modern doctors also perform the same psycho-social function, only they are immensely more successful owing to the remarkable development of potent preventive, life-saving, curing and relief-producing technology of medical science. But distortions of this very achievement have developed, influenced by economic and socio-cultural transformations. Modern medical care generated tremendous mass demand and was rapidly transformed into a commodity attaining its characteristic features. Doctors rely more and more on the infallibility of technology and are at the same time getting enamoured more and more of its commercial return. Time for consultation is now priced and cannot be wasted for demystifying, caring and personal attention. Drug industry, flooding the market with useless drugs, makes skyhigh profit so that access to essential drugs becomes dear for the poor. The very expansion of medicare services gave birth to bureaucratisation and de-personalisation. In short, while the demand for more and better medical care is increasing, escalating prices are pushing it out of the reach of most people.

Medical care continues to be one of the most pressing felt-needs of all societies. Medical care renders credibility to any health care service and ensure people's acceptance of it. China's post-revolutionary health policy is a case in point. Policy makers understood that in order to ensure mass participation in the public health programmes, the people's felt-need of medical care must somehow be met and they rapidly set up a comprehensive organisation to serve even the people in remote, inaccessible areas. To improvise, they requisitioned the services of the indigenous system of medicine. The point is to provide for some form of medical care to all regardless of standard and quality which could come later. The Chinese health system is now so organised that a citizen of a remote village is assured of the most sophisticated treatment, if needed, in an urban centre.

In our own society, preaching and practice differ. While almost everyone harps on the priority need for non-medical health care, in practice expansion of medicare service goes on unabated. Government health centres, established to provide comprehensive health care, have over the years turned into centres of curative service. People, who persistently deprecate the growing trend of setting up sophisticated diagnostic and curative centres, never fail to rush there for their own needs. The reason for this is not far to seek. Medicare needs of Indian people are so urgent and enormous that they overshadow all other needs. And their priority cannot be over-emphasised. Though it is well-known that availability of safe water is the final answer to the massive problem of diarrhoeal diseases, the instant need of the diarrhoea-stricken dying child is curative intervention and not safe water. To save the life of their dear ones, the poor risk further pauperisation, the extremely poor risk destitution. Medical care is a commodity which never fails to find consumers who cannot afford it.

To sum up, medical care is the most important felt health need of the people; medical care is the pivot of health care service; medical care adds credibility to health care programmes and ensures people's interest; medical care meets needs of the people which, though not quantifiable, are indispensable in acquiring strength to fight against adversities. And whatever role is assigned, on paper, to medical care, it will continue to play the dominant one in health care service. People's demand for more and better medical care will never diminish.

Medical Care Delivery

How then to ensure a certain standard of effective medical care to the people? At present the delivery of medical care is operated through three channels with some overlapping. Firstly, free care—through government and non-government hospitals and clinics. Secondly, indirectly paid care—through various medicare schemes for employed people, e g, ESI, government employees' medicare, corporate employees' medicare and insurance schemes. Thirdly, directly paid care—through open market which includes a few voluntary institutions. The system, as underlined earlier, has failed to provide medical care to the poor. That is why pressure on the state to provide for the deprived is mounting. The state, on the one hand, is not in a position to disclaim such responsibility for obvious political compulsions; on the other, it cannot really provide for a minimum standard of effective

medicare for the deprived population without jeopardising the existing exploitative economic order. To find the way out, several prescriptions have been offered as remedies. The ICSSR – ICMR report recommends a 6-tier organisation from the smallest unit at the lower level covering 1,000 persons operated by two part-time voluntary health workers. The required cost has been worked out to be very low, e g, Rs 30 per capita per annum. The entire scheme appears to be not only simplistic but idealistic as well. It also offers universal access for affluent and poor alike; allows private market to thrive; does not provide for guaranteed emergency care and rests on the premise that both the higher echelons of administration and the providers are imbibed with the spirit of selfless public service. Several other prescriptions include (a) people should be taught and trained in demystified principles of medical care so that they can take health in their own hands, (b) indigenous and non-allopathic systems should be adopted to develop an alternative cheaper culturally acceptable medicare for the poor. None of the alternative schemes suggests dismantling of the sophisticated modern medicare merrily operating in the market. Parallel existence of inaccessible and costly high grade and free low grade services devalues the latter and breeds demand for the high grade one. The poor are already aware of the virtue of modern medicine. True, owing to poverty, they have to go for the cheaper alternatives most of the time, but that is no indication that they love these alternatives or have reconciled themselves to using them for ever. Government experiment in West Bengal illustrates the point clearly. Government appointed homeopath and ayurved practitioners are in a few health centres. It is a common scene in those centres that they spend their days without patients while people throng to the allopathic counter even when the latter is attended by only a pharmacist. The most repugnant feature of the alternative prescriptions is the common objective that each is aimed at lightening the burden of the state. People should be made to realise that they are responsible for their own ill health and therefore must learn to take care of health hazards by themselves. Hence the slogan "people's health in people's hands". Or they ought to remain satisfied with traditionally superior, culturally compatible indigenous medicine with a few doses of cheaper but holistic homeopathy here and there. In any case, they should not bother the state for more costly modern medicare. The modern medicare system will be there but only for the privileged and affluent as usual. The alternative schemes have a common virtue. They spare the state large expenditure and at the same time see to it that its image is not tarnished.

For this purpose, a number of issues, e g, cultural compatibility, self-sufficiency, demystification, etc, have been broached in order to confuse the problem which is essentially economic. In fact, the chief contribution of modern science is to demystify the secrets of the universe—natural and biological. At the present level of knowledge, the ancient medicines stand almost totally mystified, while modern medical science has been able to demystify the phenomenon of ill health and health care to such an extent that even illiterate people now can acquire an insight into the socio-economic and biological dynamics of physical disease and its management. Self-help is another utopia. It has long been abandoned by humankind since the introduction of division of labour in social production. By no stretch of imagination does it seem advisable to consider creation of self-sufficient human beings producing their own material, biological and cultural necessities by themselves or immediate communities.

The development of state intervention in medicare has two driving forces behind it. Demand of the people on the one hand and the ruling classes' urge to acquire legitimacy and credibility on the other. V Navarro describes the relationship precisely. 'Social demands of labour' include increase of social wages, the comprehensiveness and levels of which depend on the strength of working class pressure; 'social demands of capital' include measures to smooth down and cushion the dislocation, uncertainty and dis-welfare created by the process of capital accumulation, e g, social security and health care. Navarro explains, "there is no single-factor explanation of social policy... there is no clear-cut dichotomy between the social needs of capital and the social demands of labour. Any given policy can serve both. Indeed, the social policies that serve the interests of the working class can be subsequently adapted to benefit the interests of the dominant class... the 'bias of the system' has always insured that these policies can be deflected to suit the capitalist class. Indeed, history shows that concessions won by labour in the class struggle become, *in the absence of further struggle*, modified to serve the interests of the capitalist class" (Navarro, 1976). Several spanners have been thrown into this convenient process of concession and legitimacy—fast rising cost of modern medicare, increased demands from all sections of population, increased awareness of the discriminatory distribution of state services, effect of the international slogan of Health For All, increased trade unionism among the employees of the state health services, etc, to name a few. Mere slogans and superficial measures now fail to contain dissatisfaction. It is now realised that provision for a minimum standard of medicare for all entails a magnitude of expenditure sure to undermine other state priorities determined by the ruling classes. Hence the urge and campaign for cheaper alternatives. Noteworthy is the fact that the alternatives are prescribed for only the poor. The state cannot afford to alienate the privileged classes.

What the Poor Must Demand

Underplaying of the role of medical care should stop. Such underplaying ignores the felt-need of the people. Rakku's story revealingly demonstrates that Rakku risked further pauperisation for the elusive life-saving medicare for her child; seeing the government auxiliary-nurse-midwife on her way to the city hospital, "she suddenly felt resentment towards this woman. She wondered why as a health worker she did not have

medicines for helping sick children. Why did she only have injections [vaccines] for healthy children and advice to mothers to stop having more children! Here was her child dying and this woman could not help her" (Zurbrigg, 1984). Valuable scientific advice about safe water, personal hygiene, immunisation, balanced diet, etc, do not cut much ice with the Rakkus.

Effective medical care to the poor will never be and cannot be provided for by a state geared to the interest of capital accumulation; nor can it be provided by collective humanitarian urge. India has a long tradition of philanthropic, charitable, humanitarian effort to provide medicare to the poor and such efforts have increased through the recent spurt in voluntary agencies' activities in the health field, but this has hardly made any ripple on the health scene. The deprived people will have to earn medical care; it must be demanded from the state.

A. State medicare should be exclusively reserved for the large indigent population, i e, people living below a predetermined income level. Other existing schemes of medicare be similarly reserved for the existing beneficiaries. Affluent people be left to fend for themselves. Semi-affluent people be assisted to develop their own medicare facilities through insurance system, as is prevalent in the developed countries.

B. To operate this scheme, the population will necessarily be divided into economic categories as has been for the rural rationing system. In marginal situations and in the case of exigencies persons from unauthorised categories may be entertained in the state institutions but in exchange of a price, not free.

C. Eventually other related functions will have to be modified and rationalised. For example, state expenditure on medical education will be steadily reduced to that optimum level necessary to train personnel destined for state service.

A host of objections and problems will come up in the course of implementation of this scheme. It has been argued that such a scheme is discriminatory, is not fesible and works against humanitarian principles. Surely it is discriminatory but it is a reverse discrimination in favour of the poor aiming to abolish the present discrimination and introduce equitable distribution. The feasibility of such compartmentalised service has already been established. Several such medicare services, e g, ESI, armed forces, railway, etc, have long been functioning. In Andhra Pradesh such compartmentalised public distribution service for foodgrains is being operated for the entire state. About humanitarian principles, the less said the better.

Is this scheme another alternative to meet the medicare needs of the poor? Will the state concede this demand if only its rationality and feasibility are established? The prudent answer is NO. This scheme is founded on the premise that no scheme of equitable distribution and social justice is implemented by the state in an exploitative, class divided society. A few sporadic benefits may be realised from time to time through class struggle to produce only some palliative effect. The demand under this scheme is entirely different. It does not call for some concession for a particular group. It is not only a demand exclusively for the deprived classes so that they have a concrete slogan to struggle for and organise, but also calls for restructuring of the entire medical care system of the society. Moreover, the prospect of earning an exclusive right will provide the necessary urge to struggle for it and, once achieved, the poor will be equally zealous in guarding it. Likewise, the danger of exclusive control of a state apparatus by the poor is apt to invite strong opposition and resistance. The present beneficiaries of state service will oppose it as they stand to loose an existing privilege. The controllers of the state exchequer will oppose it as it only entails increased allocation for the poor but opens up a possibility of establishing a system of accountability of the providers to the recipients. When this inevitable opposition comes, it instantly identifies the real beneficiaries, exposes the nature and utter inadequacy of the present system; it shatters the humanitaring camouflage of the state; it makes a dent in the legitimacy of the present order. In other words, this scheme envisages conflict and polarisation of the contending forces. It may act as a nexus for class struggle.

Then again, what happens in the unlikely event of the state conceding this demand? An exclusive state medicare service will necessarily render the situation conducive for the deprived classes to exercise control over it. The essence is control. Without control there is no participation. They only participate meaningfully who weild power and authority. The very exclusiveness will generate demands for guaranteed service, accountability of the providers, uniform and better standards, more state allocation for medicare—in other words, struggle for control. Struggle for control will soon make it apparent that without eventual control over the state itself, nothing could be achieved or sustained. It will soon be apparent that the fundamental problematic is political and economic. Without political control no change in the economic order is possible. Without economic change, provision of non-medical health care will remain elusive. This situation is not peculiar to health care. The same situation prevails in the other sectors of state policy, e g, education, housing, agriculture, etc. The same discriminatory practice operates under cover of universal eligibility. It cannot be reversed without political control. The way to achieve political control is struggle. It may also begin in medical care.

The Irreversible Welfare State: Its Recent Maturation, Its Encounter with the Economic Crisis, and Future Prospects

Goran Therborn and Joop Roebroek

This article describes the influence of the current economic crisis on the welfare state in the advanced capitalist countries. The authors discuss how, under the surface of welfare state growth, the political relations of force have changed in favour of those social forces advocating fundamental reappraisal of the welfare state over those supporting its maintenance or extention. It is argued that, as long as democracy prevails, the welfare state is an irreversible major institution of advanced capitalist countries. While the building of a majoritarian anti-welfare state coalition seems impossible for the forseeable future, the authors do not rule out significant cuts in welfare expenditure in some countries and specify some of the economic and political preconditions for such cuts.

(This article was originally prepared for the conference on 'The Future of the Welfare State's held in Maastricht, Netherlands, in December 1984 and is reprinted here from the International Journal of Health Services, *Volume 16, No 3, 1986.)*

RARELY in the modern history of advanced capitalism has there been a major institution that is so much talked and argued about with so little knowledge as the welfare state. Very little is known—in the sense of being digested by prevailing social scientific as well as political knowledge—of (*a*) the recent developments of the welfare state, (*b*) its part in the current international crisis, and, consequently (*c*) the future prospects of the welfare state. Given the severe space limitations of this paper, what will be attempted here can be no more than a modest contribution toward some enlightenment in these three problem areas.

Welfare State in Contemporary History

History is the mother and teacher of the future. Any attempt at an analytical understanding of future options and possibilities, therefore, has to start from a historical grasp of the present. Here we will concentrate on two aspects: the location of contemporary welfare states in state history, and the socio-economic size and ramifications of current welfare states.

Public social insurance, public health, and social care have at least a century-old history. The major international theoretician and architect of public welfare arrangements, William Beveridge, made his epochal contribution in the 1940s, and the accompanying economic theory got its major statement in 1936 wth Keynes' *General Theory*. This is common knowledge, but for an understanding of the present—and of the future—it is quite inadequate.

In fact, the welfare state as we experience it today is an outcome of the 1960s and the 1970s. In a long time perspective, the extraordinary changes, little theorised and little even noticed, of the sixties and seventies stand out.

In the relatively uneventful years of 1960-1982, overall public expenditure on the average grew by 24 percentage points in our ten selected countries. The combined effects of the two World Wars and the 1930s with its, sooner or later, ensuing turn of economic policy orientation (the arrival of Keynesianism) brought an increase in public expenditure of 16 percentage points between 1913 and 1949. In the 1950s, during the unprecedented boom, the average increase was 1.4 points, compared with 8.4 in the 1960s, and no less than 14 percentage points between 1970 and 1981.

The accelerated growth of Western states after 1960 has mainly been due to welfare state growth. In other words, the welfare state has been *the* major factor in the growth of state involvement in the life of the people it governs. No other force is comparable to it. The rather limited proportion of welfare commitments in the growth of the Danish and Swedish states is most probably in part a statistical artifact, hiding an increase in the number of public employees working in the welfare administrations of the ordinary state apparatus.

This silent change has also meant a major internal transformation of advanced capitalist states. In their everyday activities, Western states have changed from being mainly apparatuses of armed forces, bureaucratic ordering, and public transport and communication into predominantly institutions of transfer payments to households, public education, and public caring and social services. In short advanced capitalist states have in their everyday routines become welfare states. In Belgium and the Netherlands, welfare expenditure in the sense above occupied more than half of all public expenditure by 1960 (1, pp 88, 93). In Sweden this jump occurred between 1966 and 1968 (2,3). By 1981, all advanced capitalist states devoted more than half of their public expenditures for welfare state purposes, even the United States and Japan (1, pp 70). With regard to terms of public employment, in the Scandinavian states employees in education, health care, and social care now comprise between two-thirds and three-quarters of all public employment (4). (The actual figures are 62 per cent in Sweden (1981), 68 per cent in Denmark (1981), and 76 per cent in Norway (1980). All figures except employees in public enterprises operating on competitive markets.) In the Netherlands in 1977, about 57 per cent of all government and government subsidised para-statal personnel were occupied with

teaching, caring, and other social and medical services (5). (From the total of the "kwartaire sector" (5) have been subtracted private practitioners of medicine, dentistry, and physiotherapy as well as personnel in private child care.) In brief Western states have (largely) become post-bureaucratic welfare states.

Socio-Economic Ramifications of Welfare State

We have seen that the contemporary welfare state is not an elderly institution, susceptible to the ailings of old age. On the contrary, the developed welfare state is a very recent phenomenon, better characterised by the sometimes extravagant vitality of youth. In our time, the welfare state has also become a major institution of advanced capitalist societies. One expression thereof is the significance of the welfare state as a source of income. Between one-fifth (Japan) and one-third (Netherlands and Sweden) of the sum of the household income derives directly from the state. Calculated in terms of income recipients, the significance of the welfare state is even greater. By the late 1970s, old age pensioners and public employees together made up more than half of the voting-age population in Britain and Sweden, and close to half in Germany. In the United States, public employees plus recipients of social security and of social assistance constituted about 35 per cent of the adult US population in 1975 (6).

In the Netherlands, old age pensioners and public employees are not so many—roughly 30 per cent of the electorate in 1981 (7,8). On the other hand, given the massive failure of Dutch capitalism to provide employment the total number of people receiving their main income from the state is huge. In 1983, 49 per cent of all income recipients below the general pension age of 65 got their income from the welfare state, 27 per cent as receivers of social benefits and 22 per cent as public or para-public employees (9, p 320).

Welfare State and Economic Crisis

The current, now ten-year old, international economic crisis has, of course, affected the parameters of the welfare state. However, from the discrepancy noted earlier between the dramatic growth to maturity of the welfare state and the relative lack of attention to and comprehension of it, we should expect another lack of fit between real developments and the foci of prevailing public discourse. This is in fact the case. Ideologically and politically, the welfare state is currently under heavy attack. This phenomenon is most briefly summarised in the election of the militantly right-wing liberal regimes of Thatcher and Reagan, seconded by several other governments, most wholeheartedly by the Lubbers Cabinet in the Netherlands, and in the retreating positions of the Mitterrand government, of the US Democrats, the Dutch and the Danish Social Democrats, and the disarray of the British Labour Party. In social science, the way the wind is currently blowing is most directly left from the strongly increased influence and assertiveness of anti-Keynesian economics. But major social institutions can hardly be knocked down by rhetoric alone, either from electoral platforms or from academic chairs. Let us take a look at a few facts about actual developments.

Developed capitalist welfare states remain subordinated to the business cycles and the structural crises of the international capitalist economy. The current crisis has shown that generous systems of social security in themselves provide no security against unemployment. But anti-welfare statists cannot "have their grain ground" here; there is no *inverse* relationship between social policy extension and unemployment. The evidence is contradictory (Table 1).

Economic growth has become a weak predictor of unemployment, only a quarter of the variation in unemployment at the end of 1983 can be accounted for by the economic growth between 1978 and 1983 ($r^3 = 0.25$). Between the size of social expenditure (from which education has been excluded here in order to accentuate the more controversial social security aspect) and low unemployment there is a small negative relationship ($r^2 = 0.11$), as there is between social expenditure and economic growth ($r^2 = 0.12$). In other words, only one-ninth and one-eight, respectively, of variations in unemployment and in economic growth may be statistically accounted for by the extension of public social commitments.

Briefly and crudely summarising a long argument (which is developed and sustained empirically at some liength in reference 10), contrary to the McCracken Report (11) and other conventional wisdom, states can maintain a low level of unemployment even in the face of a deep international crisis, provided there is a deeply institutionalised commitment to high employment. But general Keynesian demand management is not enough; a compatible monetary policy and/or an extensive selective labour market policy is also required. And a crucial factor is non-market control over employment, whether through extensive public works and retraining as in Sweden, public subsidies as in Norway, public industrial employment as in Austria, publicly supported paternalism as in Japan, or public control of immigration in an immigrant-dependent economy such as that of Switzerland.

Combining the extension of social security commitments and institutionalised full employment commitment, Scheme I shows the typology of welfare states with regard to both employment and social security. Commitments to social security and commitments to full employment thus vary independently of each other, something that must be brought into the centre of the welfare debate and analysis. We may give our typologised countries descriptive labels:

1. The strong welfare state (Sweden), highly committed to social security and capable of preventing mass unemployment, even in the face of a deep worldwide economic crisis and a low rate of national economic growth (12).

2. The soft welfare states (Belgium, Denmark, Netherlands), generously committed to social security, but unable to control their labour market.

TABLE1: UNEMPLOYMENT, ECONOMIC GROWTH, AND SOCIAL EXPENDITURE[a]

	Unemployment	Economic Growth[c]	Social Expenditure[d]
Australia	9.5	1.8	12.8 (1980)
Austria	4.2[e]	1.8	24.1 (1980)
Belgium	14.9	1.5	32.6
Canada	11.1	1.6	15.5
Denmark	(10.6)[f]	1.6	29.0
Finland	6.2	3.8	23.3 (1980)
France	8.8	1.8	23.8
Germany	7.8	1.5	26.4
Italy	10.0	2.1	22.7
Japan	2.6	4.3	12.5
Netherlands	14.0	0.7	29.1
Norway	2.8	2.5	21.0
Sweden	3.4	1.5	(31.9)[g]
Switzerland.	(0.4)[h]	1.5	9.4 (1979)
United Kingdom	13.1	1.1	19.0
United States	8.4	1.8	15.0

Correlations: Spearman's rank order correlation
between unemployment and economic growth, r = 0.50
between unemployment and social expenditure, r = 0.35
between economic growth and social expenditure, r = 0.34

Because of the less than perfect comparability of the data, differences in unemployment rate of 0.5 per cent or less and of social expenditure of 1 per cent or less have been left out of consideration. Since the Swedish figure was lower in 1980 than 1981, Belgium alone is topranking in social expenditure.

Notes: a The selected countries are meant to be exhaustive of all advanced capitalist countries, except the smallest—Iceland and Luxembourg. New Zealand has been left out for lack of reliable employment data.

b Standardised rate of unemployment as percentage of the labour force in the fourth quarter of 1983. Data for Denmark, from Det Okonomiske Rad *Dansk Okonomi* December 1983, p 52 Direktoratet for Statens Indkob, Copenhagen 1983. For Switzerland, from *OECD Observer* 127, March 1984. The remaining countries from OECD *Quarterly Labour Force Statistics 1984*, p 76, Paris 1984.

c Average annual growth of GDP 1978-1983, in per cent. Data for 1982-1983 from *OECD Observer* 127, March 1984. For 1978-1981, from OECD *Economic Outlook* 33, July 1983, p 160.

d Public expenditure for health, social and welfare services (transfers, public consumption, capital expenditure, exclusive of education) as percentage of GDP in 1981 prices. From OECD *Statistical and Technical Annex*, Report No SME/SAIR/SE 83.02, pp 31-69. OECD, Paris, 1983 (unpublished).

e Third quarter of 1983.

f Non-standardised rate for 1983.

g The original data source had no final consumption and capital expenditure for social and welfare services. The latter have been assumed to be of the same size in relation to social transfer payments as those in Denmark. This will be seen as a conservative estimate.

h Non-standardised rate for 1982.

3. The full-employment oriented medium welfare states (Austria, Norway), giving priority to employment policy.

4. The states of socio-economic mediocrity (Finland, France, Italy, United Kingdom), distinguishing themselves neither in social nor in employment policy.

5. The full-employment oriented market states (Japan, Switzerland), dedicated to maintaining full employment but with limited commitments to social security.

6. The market-oriented states (Australia, Canada, United States) where, in spite of significant welfare state developments in recent years, the market is unequivocally given the upper hand in income as well as in employment determination.

The world of advanced capitalism is a world of wide variations in public and in individual life chances (1).

Real Impact of the Crisis

Table 2 shows that the average yearly growth of social security expenditure declined in almost all western countries under review (except in France) between 1975 and 1981. However, up to and including 1981, social security expenditure continued to grow at a respectable pace. There were considerable yearly variations, but with the exception of Italy in 1977, the United Kingdom in 1977 and 1980, Australia in 1979, New Zealand in 1980, and Sweden in 1984, in no country was there in any year an overall absolute decline, although there were declines in individual programmes, most often in family benefits (1).

For developments after 1981 we will have to resort to national data of various kinds. The Reagan administration has concentrated its cuts on the means-tested programmes for the poor, but social security (old age, disability, and survivors) benefits grew in real

SCHEME 1: A TYPOLOGY OF CONTEMPORARY WELFARE STATES[a]

Social Security Commitment[b]	Full-Employment Commitment	
	Institutionalised	Non-institutionalised
Major	Sweden	Belgium Denmark Netherland
Medium	Austria Norway	Finland France Germany Italy United Kingdom
Minor	Japan Switzerland	Australia Canada United States

Notes: a Data from Table 4 (social expenditure) and the analysis of economic and labour market policies in reference 10;

b The procedure of trichotomisation of social security commitments has been guided by a search for significant break points such that the difference between the lowest scoring country of one group and the highest scoring country of the group below should be larger than the difference between the lowest and the second lowest country of the same group

terms by 15 per cent between 1980 and 1983, and hospital insurance (for the aged) grew by 25 per cent (13, 14). In Britain under Thatcher, public expenditures on social security and personal benefits grew from £ 25.336 million in fiscal year 1978/79 (under Labour) to £ 28.444 million (in 1978 prices) in fiscal year 1982/83 (15, 16). In the Netherlands, net public transfers to households (net insurance premiums paid) grew from an average of 3.3 per cent of national income in 1976-1980 and 4.6 per cent in 1981 (when the Social Democrats took part in the government) to 5.0 per cent in 1984, exclusive of the growth caused by the rise of unemployment (and of unemployment compensation) (9, p. 157).

But figures do not always tell the whole truth. The welfare state expenditures are still growing, but this is not to deny that painful cuts and redistribution measures from labour to capital and from the poor to the well-to-do are being made by governments. This is true not only for right-wing liberal regimes, but also for coalition governments with social-democrat participation. The measures are nearly the same in most Western countries: (a) changes in indexation of benefits, implying less than full compensation for price increase; (b) more strict entitlements to benefits, such as unemployment insurance and taxed paid services; (c) certain tendencies toward privatisation, e g, a relative increase in number of beds in private hospitals compared with public hospitals, and accommodation of public-controlled services, especially in the sector of health services, to the private sector; (d) a tendency toward de-individualisation of rights on social insurance and restrengthening of the "family breadwinner principle" in entitlements to social insurance; (e) rationalisation, especially in the health services; and (f) shifting costs: less redistribution over the public budget and more emphasis on direct payments for services and insurance premiums. In Belgium, the Netherlands, and the United Kingdom these measures are accompanied by a discussion about a more fundamental reappraisal of the system of social security on the basis of actions taken by the government.

TABLE 2: ANNUAL GROWTH OF THE EXPENDITURES ON SOCIAL SECURITY[a]

	Percentage Growth		
	1965-70	1970-75	1975-81
Australia	5.3	15.6	2.8
Austria	6.4	5.8	4.6
Belgium	9.1	10.5	5.1 (1975-80)
Canada	11.5	12.9	3.3
Denmark	9.0	6.6	4.5
Finland	10.7	9.5	5.5
France	5.0	6.6	7.4
Germany	5.5	8.6	2.0
Italy	8.2	6.5	3.9
Japan	10.4	12.3	8.6
Netherlands	11.6	8.3	4.5
Norway	15.3	8.0	6.2
Sweden	10.2	9.6	4.4
Switzerland	8.9	10.4	2.7 (1975-79)
United Kingdom	5.3	6.3	3.9
United States	9.3	9.9	3.7
Average	9.4	9.2	4.6

Note: a Calculated from reference 1, in constant 1970 prices. Expenditures on health, temporary sickness, pensions, unemployment, family benefits, and other transfers.

With regard to the welfare state as a whole, the real impact of crisis policies has so far been marginal and unable to break the trend of growth. But it is worthwhile to investigate if these policies reveal recent changes in the political relations of force.

Welfare State and Political Relations of Force

The explosive growth of the welfare state in the sixties and early seventies is accompanied on the political plane by a strengthening of the position of labour *vis-a-vis* capital. This is the effect of wide-ranging social processes that have undermined partriarchy and the family control over production, challenged clientelist and religious forms of social control of production and class division, increased the scarcity of labour on the market, and diminished the dependence of the propertyless upon the labour market for their support (17). This development resulted in a compromise of the main political actors, wherein the welfare state provisions occupied an important place.

What happened to the political relations of force from 1975 onward? In most countries the crisis policies cracked the existing compromise. To answer the question more carefully, we have made, for a selected group of Western countries, a more thorough analysis of government social policy in the crisis.[6] (The analysis is based on materials from the project *The Political Future of Social Security: Political Demands and Social Relations of Force*, financed by The Commission for Research on Social Security (COSZ) of the Dutch Ministry of Social Affairs and Employment.) As a first result, we present two schemes. Scheme 2 contains an overview of the points in time at which a "crisis statement" is given, the "first significant cuts" are carried out, and the discussion about a more "fundamental reappraisal" of an important part of the welfare state, the system of social security, begins. Scheme 3 reveals the composition of the government at these points in time.

At the time of a "crisis statement" (and also of the "first significant cuts"), with one or two exceptions (Netherlands and Sweden) the social democrats formed a coalition government (in Belgium with the confessional and liberal parties) or took a dominant position within the government. Second, discussion about a more "fundamental reappraisal" of the system of social security and the launching of plans in that direction took place exclusively under right-wing governments. In the two countries where the discussion was advanced and the governments proposed plans for the reappraisal, the right was, in a relative sense, best represented in the governments that announced the "crisis statement" and carried through the first "signifi-

cant cuts." In the three countries where the discussion was started by conservatives and liberals (Denmark, Germany, and the United Kingdom), social democrats were defeated in an election after a (long) period of governmental power and were sent back to the opposition. These developments indicate that under the surface of a relatively unbroken growth of the welfare state, a change of the political relations of force has taken place: a development that needs more attention with regard to the future of the welfare state.

This shift in the relations of power should not be understood as an exclusive effect of changes in electoral favour. It is a more structural development not only of social and political relations, but also of social and political moods. It is a field of forces in which political parties, labour unions, employees organisations, and other organisations try to influence decisions that are made within the government, the parliament, and other organs. In this field one can, in general, distinguish two fronts with regard to the welfare state: on the one hand the organisations and forces that advocate a fundamental reappraisal of the welfare state, and on the other hand the organisations and forces that stand for maintenance and, where necessary, further extension of the welfare state. The first front is composed mainly of the conservative, the liberal, and larger or smaller parts of the confessional parties, the employers' organisations, and sometimes middle-class organisations. The other front is made up of the social democratic, communist, and other progressive parties, the labour unions, and organisations of consumers of services and recipients of benefits. The development in the relations of force since 1976 indicates a shift in the direction of domination from the "maintenance front" to the "reapparaisal front" (Scheme 4).

We can come to the more general conclusion that the resistance to significant changes within the welfare state, even when there is domination by the "reappraisal front", is so strong that a fundamental reconstruction of the welfare state is excluded. Even in the Netherlands, it is not obvious that the defeat of the trade unions in December 1983 weakened the position of the "maintenance front" to such an extent that the announced reconstruction of the social security system will be carried through.

SCHEME 2: THE POLICY OF WELFARE: A SEQUENCE OF ACTIONS

	Crisis Statement[a]	First Significant Cuts[b]	Fundamental Reappraisal[c]
Austria	1983	—	—
Belgium	1976	1980	1983
Denmark	1980	1980	—
France	1982	—	—
Germany	1975	1977	—
Netherlands	1978	1980	1983
Sweden	1980[d]	—	—
United Kingdom	1976	1977	1983

Notes: a "Crisis statement" refers to the moment that the government announces that the policy of welfare cannot be continued without changes.

b As a criterion for "first significant cuts" we use three standards. First, two quantitative standards: an annual growth of expenditures on social security of less than 2 per cent and/or a decline in the annual growth rate of more than 3 per cent. Also a qualitative standard: the changes in a quantitative sense are the result of obvious alterations in policy. This estimation is based on materials up to and including 1983.

c "Fundamental reappraisal" refers to the statement by which the government takes the initiative for a possible fundamental change of the social security system as a whole. This is usually done through the setting up of a public commission of investigation with far-reaching tasks.

d In Sweden the "crisis statement" was made by the incumbent bourgeois government in 1980. After the reelection into office of the social democrats in September 1982, the social cuts that followed the "crisis statement" were redrawn and did not take effect.

SCHEME 3: THE POLICY OF WELFARE AND THE COMPOSITION[a] OF THE GOVERNMENT

	Crisis Statement	First Significant Cuts	Fundamental Reappraisal
Austria	left	—	—
Belgium	coalition	coalition	right
Denmark	left	left	—
France	left	—	—
Germany	left	left	—
Netherlands	right	right	right
Sweden	right	—	right
United Kingdom	left	left	right

Note: a Here we use a threefold distinction: "right" (conservative-liberal-confessional), "coalition" (social democrats in a balanced coalition with one of the right-wing parties), and "left" (a government dominated by social democrats).

Future of the Welfare State

On the basis of the evidence given earlier on the socio-economic ramifications of the welfare state, and further sustained by the record of the effects of the welfare state upon the economic crisis, we conclude that the welfare state is an irreversible major institution of advanced capitalist countries. Or, to be more precise. It is irreversible by democratic means. The size of the population benefiting from the welfare state ensures that as long as democracy accompanies advanced capitalism, the core of the welfare state is safe. This goes against a great deal of hopes on the right and fears on the left. But it is not enough. We have seen above that the welfare state is a variable, not a fixed, entity; an assessment of its possible future will have to pay attention to possible variations. Our general analytical perspective involves two fundamental causes of welfare developments: socio-economic tendencies and socio-political relations of force.

The major push ahead of the welfare state is the aging of the population of advanced capitalist countries, except that of Belgium. The aging of the population means not only more pensions and more old-age services, it also means a great increase in health care. For the Netherlands, it has been calculated that for the period between 1981 and 2000, a growth of expenditure (for pension benefits, nursing homes, old people's homes, old people's welfare work, and medicines) of

more than 20 per cent is needed to maintain existing standards (18).

A second push for welfare state expenditure derives from unemployment. Currently, almost all predictions point to an enduring rate of massive unemployment among two-thirds of advanced capitalist countries, which have failed since 1975-76 to maintain more or less full employment. This means the establishment of a virtually permanent pool of unemployed. Except in Belgium, existing unemployment insurance is not geared to handling long-term and permanent unemployment. Under existing political conditions, permanent mass unemployment is likely to produce mounting pressure for economic provision for the long-term unemployed at a level above that of social assistance.

A third major pressure for increased public social commitments may be expected from population concerns. In most Western European countries the current rate of reproduction is negative, and it may be expected that procreation-stimulating social policies will be adopted. The Sweden, this is already a consensual issue.

Fourth, the number of single mothers is likely to increase. Particularly in countries with current high unemployment and low rates of female participation in the labour force, this implies an increasing demand for social assistance.

One significant alleviation of the pressure is the visible tendency of expenditure for public education to decline because of demographic changes in Western populations. For the Netherlands, this means a possible decline of expenditures between 1981 and 2000 of 20 per cent while maintaining the existing level of education (18, p 86).

The fiscal constraints of social policy are not absolute givens. They are to a large extent politically defined and affected by policy outcomes. The enduring crisis does not mean a permanent depression, as shown by the current upturn in which a growth rate of 2.5 pr cent is forecast in 1984 for the European Community and 4.5 per cent for the.OECD as a whole (9, p 19). A provisional calculation by the OECD Secretariat for the seven major Western countries estimates that, because of declining needs for education expenditure, a constant GDP share of welfare state expenditure could ensure a 0.7 per cent annual growth in real social benefits till 1990 (1). One the whole, and by and large, there seems to be little reason for doubt that the current level, or even a moderately higher one, of social welfare commitments is payable.

However, there are at least two qualifications to be made here. Pensions insurance schemes in many countries are very sensitive to lower rates of growth and/or to high rates of employment. In some countries revisions have already been made, and further ones are not unlikely. Second, some countries have already incurred large financial deficits in their public sector. The mounting interest burden of this debt and the narrowed policy margins of big structural deficits are most likely to constrain furture social policy. This holds, above all, for Italy and Belgium, but also to a lesser extent for Denmark, the Netherlands, Canada, and Sweden (16, p 27).

SCHEME 4: CHANGES IN THE RELATIONS OF FORCE BETWEEN THE "MAINTENANCE FRONT" AND THE "REAPPRAISAL FRONT"[a]

	Domination Maintenance Front	Balanced Relations	Domination by Reappraisal Front
Austria	1975-1982	1983-present	
Belgium		1975-present	
Denmark	1975-1980	1980-1982	1983-present

	1982-persent		
United Kingdom	1975-1976	1976-1979	1979-present

Note: a This overview has been made on the basis of electoral results, changes in the composition of governments, actions to economise, and the results of confrontation between both fronts.

Socio-Political Forces of Welfare State Demands and Defence

At least one major social force behind the welfare state is growing and is likely to become more active and demanding in the future: that is old people, the "senior citizens." They are growing in numbers, and they are becoming more vital and active because of the combination of increased longevity and reduced retirement age. The aged are also by far the most important beneficiares of the welfare state. Pensions and health care of the aged make up the bulk of social security expenditures in all countries. As the French specialist Anne-Marie Guillemard has said: "The welfare state is, first and foremost, a 'welfare state-for-the-aged'" (19). The demands of the aged are likely to grow for social, cultural, and recreational services, and the aged are likely to be vigilant with regard to their pension rights and level.

Another interested welfare state defender is the group of welfare state employees. Their number is unlikely to grow in the near future, but it is quite significant already, between a quarter (in Sweden) and a tenth (United States, Germany, and Italy) of the economically active population (20). This is a well organised and highly articulate category of people. Welfare state employment has been especially important for the emancipation of women, who usually occupy most of these jobs. Large-scale attacks on the welfare state are therefore likely to meet with resistance from articulate women, even those outside welfare-state employment.

Finally, the labour movement is in modern times the major political protagonist of the welfare state. In countries with high unemployment, the labour movement is currently being weakened, and tendencies to division between private and public employees are appearing. However, even after some recent setbacks, the labour movement in most advanced capitalist states is

located on a historically high plateau of strength and acquired rights (17).

Precondition of a Right-Wing a Roll-Back

We have given a number of reason for our conviction that the welfare state is irreversible by democratic means, and also for our belief that in the foreseeable future even successful cuts and restrictions will not change its fundamental base. However, countries already vary in their line-up for or against the existing welfare state and further variation cannot be excluded. On the contrary, there are strong grounds to expect a further divergence among advanced capitalist states over the coming five to ten years. This divergence derives mainly from the divergent impact of the current economic crisis, in particular with regard to unemployment. The enormous differences in the rate of unemployment (shown by Table 1) are likely to have an enduring, diverging impact for two reasons. First, all OECD estimates indicate that these differences will remain for the rest of the 1980s (21). Second, and also an explanation in part for the first reason, contrary to pre-crisis predictions or fears, mass unemployment has not led to massive socio-political upheaval. Mass-unemployment Netherlands remains as calm as low-unemployment Sweden.

Before going further, however, a major qualification has to be made. Politics and policy are not amenable to scientific prediction. Rather than expecting their specific predictions to come true, political scientists would do well to adopt as a major law of politics the title of a book of stories by Andre Maurois, *Toujours l'inattendu arrive* (always the unexpected happens). We should formulate all of our predictions as conditionals: "if *a*, then (probably) *b*."

The fundamental precondition for a significant right-wing roll-back of the welfare state is a division, a demoralisation, a decomposition, and an at least partial political marginalisation of the broad coalition of socio-political forces that supported and sustained the welfare state expansion in the 1960s and 1970s. The building of a socially majoritarian anti-welfare state coalition, dedicated to capital accumulation and to private business ideology seems impossible in the foreseeable future. The best evidence for the latter assertion is given by the comparative class analysis of Erik Olin Wright. Wright combines the scientific commitment of Althusserian Marxism with post-orthodox theoretical sophistication and the large-scale empirical surveys of American Big Science. His results indicate that even in the United States, about 60 per cent of the labour force has at least a minimum of pro-labour or working class consciousness. In Sweden the corresponding figure is 90 per cent (22, 23).

What then are the preconditions for a division, demoralisation, decomposition, and partial marginalisation of the welfare coalition? First, high unemployment and/or other kinds of worsening in the condition of labour, incurred under a government in which the major left-of-center party takes a significant part. The record of the successful low-unemployment countries strongly suggests that such a major policy failure is not primarily due to the openness to and force of the international economic system, but to half-hearted, contradictory, or adverse policies. The electoral defeats of British Labour (in 1979), of the US Democrats (in 1980), of the Danish Social Democrats (in 1982), and the Dutch center-left (in 1982) fit into this pattern, as does the current defensive of the Mitterand regime. However, the original division and demoralisation of the forces of the left and the center-left have to be reproduced for the right to be able to make significant inroads into the welfare state. There are a number of possibilities for this reproduction, which are not mutually exclusive.

Second in our list of preconditions, and the strongest and most reliable mechanism for reproducing division, demoralisation, and decomposition of the left, is a dualistic scoio-economic development. A dualistic economy and society—a dynamic, well-off sector and a stagnating or declining sector of low-wage or unemployed misery—is the medium-term goal of the new right, consciously or unconsciously. And the fact is that some advanced capitalist societies are beginning to take on those features earlier held to be characteristic only of Third World societies. Thus in Britain, an increase of unemployment from 5 per cent in 1979 to 12 per cent in 1982 was accompanied by a slight increase of consumer expenditure, measured in constant prices (24). The US economy grew by 7.6 per cent between June 30, 1983 and June 30, 1984, but unemployment was still 7.1 per cent at the latter date (25). The more a dualistic economy and society is created, the stronger the roll-back pressure on the welfare state. The current upturn of the international business cycle is likely to produce significant dualistic effects even in societies and politics not so extreme as those of Britain and the United States. The economy is also beginning to grow again in Belgium, Canada, Denmark, and the Netherlands, but mass unemployment and the misery of the unemployed remains.

Managing a dualistic economy and society by democratic means is largely dependent, however, on the character of the political system. This is our third variable: the more elitist the political system, the easier a right-wing attack on the welfare state. One important measure of elitism is the prevailing electoral turnout. In this respect, the Western democracies currently fall into three groups (26).

1 The exclusive democracies, with an electoral turnout of about 50 per cent of eligible voters: Switzerland and the United States.

2 The reduced participation democracies, with a 70-85 per cent participation rate: the United Kingdom, Japan, the Netherlands, Finland, Denmark, Norway.

3 The full participation democracies: the remaining countries.

Elitist politics, reinforced by first-past-the-post electoral systems, mean that Thatcher and Reagan were elected into office by less than a third of the electorate.

Finally, there are policies reproducing left-wing

defeat. We began our list of variables conducive to right-wing attacks on the welfare state by indicating the fateful effects of anything less than whole-hearted commitment to full employment in the period 1975-1982. We will end it by listing a set of policies most likely to ensure the reproduction of the dominance of the right. From the point of view of the right, the policies may be read as goal targets.

1 Disunity between trade unions and the political parties representing labour. The greater the disunity, the greater the chances of a right-wing roll-back. This is partly a question of institutional structure—the extent of elitist middle-class character of the party, which is thereby starkly distinguished from the unions. The US, British, Dutch, and French cases indicate this. But it is also something that is affected by policy, as exemplified by the *Schulterschluss* between the Social Democratic Party and the unions in Germany after the eviction of the Schmidt government.

2 Concessions from a weak position in the hope of reciprocity. Givebacks of collective-bargained wages and other benefits in a weakened position are likely to produce mainly internal division and demoralisation, and unlikely to bring forth equivalent concessions from the counterpart. This tactic has been pursued by some US unions—that of the steelworkers above all—and, en masse, by the Dutch unions, seconded by the Dutch Labour Party. The main effect of this is likely to be a strengthening of the self-confidence and assertiveness of the political right and of the employers. The West German unions and Social Democrats have, after losing office, opted for another tactic, the result of which is more respect for the concerns of labour.

3 Selective social policies. There is a dilemma in social policy between general and selective policies. In order to be effective and truly general, general policies have to be high in transfer payment and in quality of services. This makes them very costly and also tends to reduce their redistributive effects. On the other hand, selective social services tend to be or become of lower quality, and selective social policies are or become very vulnerable to political attacks, since the set of beneficiaries is restricted. Therefore, the more selective (geared only to the poorest) the social transfers and social services, the more likely they are to be subject to roll-back attempts. Thus, to the extent that left-of-center parties and trade unions adopt selective social policies, e g, in the form of "basic" services and transfers plus optional superstructures, the more likely it is that the level of the "basic" provisions will become the object of attack.

4 Decentralised labour policies. The strength of the labour movement, and of the welfare coalition as a whole, rests on its numbers and its unity. To the extent that policies are adopted that are not based on those assets, the right and the anti-welfare state coalition will gain. This implies that the more collective bargaining is decentralised, and the more specificities of private and public sectors, of industrial branches, and of enterprises are opted for in the current period, the stronger will be the position of capital, and of the anti-welfare state forces.

The welfare state has become a major and irreversible (by democratic means) feature of advanced capitalist societies. The current discussion of the welfare state crisis is little more than an ideological fad, which serious researchers cannot take seriously. On the other hand, a divergence of Western welfare states is likely to take place in the foreseeable future. The failure to maintain full employment that began in 1975 is likely to have enduring effects. Further, the reactions to the earlier failures diverge. The West German labour movement seems to have learnt from its past, whereas in the Netherlands, for example, we see strong left-of-center forces heading for further defeats. However, we would rather end by saying that the future remains open. As political human beings, we are committed to full employment and to social security.

Sex Determination Tests

A Survey Report

THE practice of prenatal sex determination followed by selective female foetus abortion is one of the most striking examples of how advances in science and technology are employed for the furtherance of women's oppression. Although this inhuman practice has been in existence in India for many years, it is only last year that anything like an organised and sustained mass campaign against it became a reality. While Bombay has been a principal centre of the campaign, it has now also spread to other cities, including some small towns. A concrete manifestation of this positive change has been the formation of the Forum Against Sex Determination and Sex Pre Selection.

The collective efforts of several women's groups and other voluntary organisations, spearheaded to some extent by the Forum Against Sex Determination and Sex Pre-Selection, have yielded some notable results. Two private bills concerning this issue were introduced last year—one in Parliament and the other one in he Maharashtra legislature. This goes to prove that both the Union and the state governments were forced to take note of the issue because of the growing popular protest. The bill in Parliament is yet to come up for discussion. Nevertheless, the minister of state for health and family welfare did convene a meeting in New Delhi last December to discuss the issue. The Maharashtra government formed a committee in September last to study the problem and suggest a set of corrective measures. The private member's bill in the legislature came up for discussion in the 1986 winter session at Nagpur, but the same was withdrawn following an assurance from the government that the committee was still studying the problem and that, on the completion of the study, the government would itself initiate appropriate action in the matter.

As part of its activities, the state government-appointed committee commissioned me for the Foundation for Research in Community Health (FRCH), Bombay, to conduct a short study of the prenatal sex determination tests and female foeticide in Bombay city. The study was conducted in November 1986 with the objective

a) Determining the extent of the spread of sex determination tests and female foeticide in Bombay city;

b) Finding out other related aspects of this practice; and

c) Knowing the views and perceptions of the doctors involved in this practice.

Fifty private gynecologists, chosen randomly but with a view to covering the entire city and the suburbs, were interviewed in person during the course of the study. Some of the important findings of the study were:

1 Eighty-four per cent of the gynecologists perform amniocentesis for the purpose of sex determination. These doctors together perform on an average 270 aminocentesis tests per month.

2 Some doctors have been performing aminocentesis for the past 10-12 years. But a majority of the doctors (over 85 per cent) have started performing these tests in the last five years. On the one hand, this shows that Bombay is one of the first urban centres where SD tests and female foeticide started. On the other hand, it is evident that the debate that took place in the early 80s had a significant anti-publicity effect.

3 Only very few (upto 5 per cent) of the aminocentesis tests conducted are done for the detection of genetic defects.

4 Seventy-five per cent of the doctors interviewed said that over 50 per cent of the women who come for the tests belong to the middle class, whereas 85 per cent of the doctors said they do not get women from the lower classes for SD tests.

5 It is generally believed that it is only women with four or five daughters who go in for SD tests and female foeticide. But the study showed that the proportion of women going for SD tests when they have four or more daughters is quite small and that a majority of the women coming to the SD clinics are mothers of two or three daughters. Significantly enough, 24 per cent of the doctors said that 20 per cent of their patients had only one daughter. Thus, it appears to be a growing trend among the public to go in for SD tests in the second pregnancy itself, if the first issue happens to be a girl.

6 About 30 per cent of the doctors said that in nearly 10 per cent of their cases, the women already had one or more sons when they came for SD tests. This findings explodes one more myth that only those women go for SD tests who have no sons and only daughters. This trend moreover, appears to be on the ascendancy.

7 A majority of the doctors contacted in the study see SD tests and female foeticide as a humane service to women who do not want to have any more daughters. Some doctors also fee that SD tests and selective abortion of female foetuses are a good method of promoting family planning and controlling population growth in the country.

8 Six out of the 50 doctors said that they also per form chorion villus biopsy for sex determination.

—Sanjeev Kulkarni

Isolate Apartheid Health Care

THE Anti-Apartheid Movement in Britain has been campaigning for the isolation of the racist apartheid regime in all areas—political, economic, cultural and sporting for 27 years now. It has been realised that the policies of apartheid in segregating health care in South Africa and the inaction of the authorities in the face of rampant malnutrition and preventable disease amount to state-directed genocide against the country's black majority.

Recognising this and that health is an emotive issue which effects everyone and that everyone can therefore relate to, in 1979 health workers within the Anti-Apartheid Movement joined together to form a Health Committee. The mandate was to use health as an issue to educate people about apartheid and to mobilise health workers to support the international boycott. Since then Health Committee members have researched the health situation and produced campaigning leaflets, documents and a newsletter on health in South Africa. We have travelled up and down the country speaking at meetings and mobilising people in the struggle against apartheid.

Health and Liberation our newsletter is produced quarterly and covers the latest update on health in South Africa as well as news of our campaigns in Britain.

Exchange of medical skills in knowledge between Britain, South Africa has gone on for many years. British nurses are recruited to work in South Africa, lured by the prospects of sun, sea, sand and higher wages. The need for them lies in the racist ruling that black nurses may not care for white patients. Thus whilst black nurses, unemployed are relegated to the Bantustans, white British nurses are recruited to make up the shortfall of staff for the whites-pnly hospitals.

Many medical students go to South Africa for three months 'elective' period as part of their training and many doctors go to work there for short periods. These people are attracted by the regime's publicity that pathology can be seen in South Africa at a more advanced stage than elsewhere in the world. This is true, but it shows the true callousness of the regime that it can use the misery of the nation's black majority—created by their denial of facilities for the prevention and early detection of disease—as a way of attracting people to break the international boycott and make up the shortfall in doctors which has arisen through the denial of adequate places for training African people as doctors. To all these groups of health workers we have directed specific campaigns not to go to South Africa to work or on lecture tours.

Our international work to gain the expulsion of South Africa from international medical bodies began in 1981 when the Medical Association of South Africa (MASA) applied to be readmitted to the World Medical Association. A major international campaign was conducted with extensive briefing documents circulated covering the medical treatment of Steve biko and the inability of MASA to address itself to the collaboration of doctors with the security police and the inequalities in and fundamental issues behind health care in South Africa. International opinion was mobilised against MASA. The campaign culminated with MASA's readmission solely on the basis of the voting system which is loaded towards the United States. However all the African countries resigned, the WMA lost its consultative status with the WHO and in 1983 the British Medical Association withdrew. The WMA was thus left as an impotent and unrepresentative body.

A similar campaign was conducted at the International Planned Parenthood Federation which ended with South Africa's resigntion in July 1986, and currently we are campaigning for South Africa's expulsion from the World Psychiatric Association and the International Dental Federation.

Another important facet of the struggle against apartheid is direct material solidarity with the liberation movements. With this in mind we established the Medical Aid Campaign for Southern Africa to collect money for medical supplies for the ANC and SWAPO. We have sent a large amounts of books and drugs to the ANC hospital in Tanzania at the Solomon Mahlangu Freedom College and to their clinics in Zambia and Angola.

Over the coming few years, the struggle in South Africa will be reaching its most crucial stage and with this comes an ever more urgent need for concerted international action to gain the total isolation of the apartheid regime and the final victory against the forces of racial and national oppression in South Africa. Health workers throughout the world must unite with this goal to contribute in a small way to the final victory.

Secretary AAM Health Committee

Towards Rational Therapy

THE Prescription Guidance and Information Services (PGIS) of LOCOST is an educational effort to promote awareness about the correct use of medicines. PGIS is therefore for the benefit of both prescribers as well as patients. Two main aspects of PGIS being proposed are:

(1) Information dissemination to doctors who write prescriptions and
(2) Guidance to the patients regarding the correctness and use of medicines prescribed in a particular condition.

The objective here, is to help the patient, the end user of medicines to know the correctness of the medicines prescribed. the PGIS will give comments on following aspects of prescription: correct medicine for a particular diagnosis, adequacy of the treatment, the uselessness or harmful effects of any medicine, the side-effects of the medicines required, the dosage, alternatives available both in terms of cost, quality and nature of medicines, etc. Wherever possible, other aspects of the therapy will also be explained. This will

help the patient by developing an understanding regarding the treatment given to him/her. This will also equip the patient and relatives or friends to question and to ask for more information from prescribers in future. Thus the ultimate aim is to build up consumer awareness and initiative to bring about a change towards more rational therapy.

LOCOST is aware of the limitations of PGIS: Personal examination of the patient may not be feasible, the scope of PGIS may not cover all diagnostic situations as also the fact that a large number of 'successful' treatments may not be touched, and so on and so forth. The service may not be useful for the patient as it will take at least 10-15 days to give a balanced view on the prescription. However, queries by doctors for information can be attended to faster. LOCOST is keen on not encouraging legal battles between the patient and the doctor. PGIS is a beginning, a collective effort to facilitate awareness, education and action. Action towards more rational therapy and towards conserving scarce resources of patients as well as that of the community.

LOCOST is also prepared to facilitate prescription medical audits of hospitals, dispensaries and community health projects, if so requested. You may be a like minded doctor, a patient or a person simply interested in social change. Contact: *Prescription Guidance and Information Service (PGIS)*LOCOST, Ist Floor, Premanand Sahitya Sabha Hall, Opp. Lakadi Pool, Dandia Bazar, Baroda 390 001.

Miracles and Profits in Sickness

A NURSE who focussed a small research project for a post-graduate university course on a private food allergy clinic managed to achieve a relatively high mark from the tutors involved, and it was also considered worthy of publication in a scholarly journal. To her amazement the doctor whose clinic had been studied objected to the publication, not because of any feared damage to his professional reputation, but because of certain implications seen behind the student's work—especially the open discussion of the sordid subject of money.

There are a number of diseases where medical science has not discovered or developed a method of entirely halting their progress and treatment is limited to controlling or alleviating the symptoms, but not the spread of the disease itself. These conditions typically attract imaginative mirage "cures" which are difficult to get, expensive, or both. The cure is often proclaimed as some commonplace naturally occurring substance—igonred by modern western technology—which, according to anecdotal claims, has been used for years in a remote part of the world. Sometimes the product or treatment method is a secret which cannot be disclosed to the general public, but you can always buy bits of the magic. Whatever the story, evaluation by independent scientific workers will prove fraught with snares and delusions.

If some unfortunate person whose name has publicity value falls ill, (s)he may be treated with the remedy and live happily ever after. Recently a former pop singer, hitherto not widely known but nonetheless of some public interest, fell ill; and her symptoms were attributed to multiple allergies. Personal friends and a sympathetic section of the public expended much good will, time and effort in what appeared to be a good cause. The patient was flown to Dallas, USA, to Dr Rea's Environmental Unit, but her luck did not continue; voluntary funds of sympathisers at home dried up and she was not shown returning home in triumph. She returned as she had left—on a stretcher with an oxygen mask attached to her face, as she inhaled the only unpolluted vapour she could tolerate.

It has been said that "A fool and his or her money are easily parted"; sadly many patients would seem to be fools, if judged by the large sums of money they seem willing to pay for treatment of very doubtful value. Maybe it doesn't matter what treatment patients have if their belief in it is enough to effect a cure, but the long-term consequences of 'miracles' have also to be considered.

What happens when the dream fades, when the symptoms return or new ones come in their place? The despair and frustration must be magnified, as the patient has once again to struggle with a handicapped identity. Having attended an unorthodox clinic the patient may not only be financially broke but, more difficult to repair, psychologically damaged by the disappointed dreams offered by modern medical messiahs.

It costs a lot of money to run private clinics, and to pay attractive salaries to people who remove themselves from incremental ladders in the NHS, and need financial incentives to get involved in work that is of doubtful validity within scientic medicine. It is not difficult to find private practitioners from various disciplines who will quite readily remove NHS equipment and surgical supplies to "get their clinic started." When they are challenged about this exploitation of the health service, one is reminded that the patients who attend the private clinic cannot be treated by orthodox methods and as they are paying their NHS contributions it is all OK. While a hospital porter may get taken to court for removing flowers from a tip outside the hospital, the consultant who sends a junior nurse down to surgical stores to collect an expensive piece of equipment is able with impunity to 'transfer' the hospital instruments to the private clinic and reap the benefits from the fee-paying customers.

Doctors and nurses who work in private clinics using untested methods which are either innocuous or dangerous, are prostituting themselves by capitalising on the dignity and prestige afforded by their medical or nursing qualifications. It is indefensible to take advantage of the trust patients place in health care practitioners, and to make financial gain out of their vulnerability.

Towards a Left Critique of New Drug Policy

anant r s

The long awaited new drug policy has prompted this piece so that RJH-readers may get some systematic idea about this issue, especially its economico-political aspect, albeit in a summary form. For a detailed treatment of the basic issues involved in the drug policy, readers may refer to some of the sources at the end. A special issue on Pharmaceuticals and Health is being planned in December, 1987 and will carry a substantial left analysis of issues in drug policy.

THE NDP represents a typical example of the 'new' thinking in the ruling class circle and the new method of functioning. First about the latter. A lot of show was made about consulting various experts and of giving a hearing even to the representatives of the All India Drug Action Network. (AIDAN). But all this facade meant nothing in practical terms; or perhaps the drug industry used 'tonic-M' much more liberally this time. The NDP was suddenly announced in a hurriedly convened press conference; bypassing the Parliament. The 'policy' consisted of only a breif statement amounting to about 1500 words—That's all!! When a lack of a detailed draft was criticised by all analysts, the government came out with a somewhat detailed 19-page announcement. When one reads this pamphlet a little carefully, it is clear that it was written *after* the 'policy' was announced. The press statement of the December 18, 1986 was not a summary of a policy document since no such document was ready the then.

For example, the press statement of December 18 says that. "A National Drug and Pharmaceutical Authority will be created. This authority will be an apex body which will have representation from all the concerned agencies including those from the industry. Among other things, it would go into the question of rationalisation of existing fomulations in the market including the banning of formulations of harmful nature. . ." When one looks for an elaboration of this point in the detailed policy announcement, to one's utter dismay and shock there is not even a mention of "representation from all the concerned agencies" nor of "banning the formulations of harmful nature"!! To release a brief statement to the press and then to prepare the main text is a mockery of the norms of even bourgeois democracy. The deletion of these to small concessions (announced in the press statement,) given to the movement for a Rational Drug Policy was perhaps on account of bowing to the pressure exerted by the drug industry to scrap these concessions. To silently drop certain measures already announced is shocking indeed.

The earlier policy of 1978 was based on the report of the famous Hathi Committee which had at least a few Members of Parliament (though there were no representatives of the concerned trade unions and of consumers.) The policy-making was done this time entirely by bureaucrats and technocrats. The Drug Consultative Committee of the Parliament was not involved. The content of this NDP is therefore as bad as its flimsy form. None of the issues central to the Drug Policy have been seriously considered except the ones related to profits and production increase. All the important issues have been adequately highlighted by different science and health groups, some of which were dealt with by the famous Hathi Committee more than a decade back. Instead of making progress beyond the Hathi Committee there has been a regression right from the basic stage. It is, therefore, not much of a surprise that the content of the policy is also reactionary.

Freer Hand to Multinational Companies

The drug industry in India in under the domination of the MNCs. The various ill-effects of these MNCs have been adequately proved by different studies—commercial exploitation of Indian consumers through transfer-pricing; huge outflow of capital through repatriation of profits in different forms, drain on the foreign-exchange account; huge social waste on account of extravagant selling expenses, disinformation of doctors, insistence on brand-names, production of irrational and hazardous drugs when the same drugs are not allowed in their parent country, etc. It is because of these ill-effects that the Hathi committee had recommended nationalisation of these MNCs. The Hathi committee's recommendation did not include confiscation (i e, nationalisation without compensation) or worker's control along with nationalisaton. But even this radical bourgeois recommendation was not accepted by the Indira government.

The New Drug Policy has on the contrary given further concessions to the MNCs. "For the production new bulk drugs, and drugs produced for exports, there will not be any restrictions on the MNCs, even though it is well known that MNCs tend to import penultimate products from their parent-companies at extravagant prices and hence are responsible for a drain on the Indian economy even for foreign exchange account. Production of penicillin, amoxycillin, cephalexin etc, has also been completely decontrolled except for FERA companies." But the hitch is, there are now only 3 FERA companies; the rest of the MNCs have now become 'Indian' because they have diluted their foreign-equity to less than 40 per cent as per the FERA. Out of these eight a further six have announced their intention to dilute their foreign-equity to less than 40 per cent, so that like in other ex-FERA companies, the foreign share-holders would continue to take all the policy-decisions but the company would now be legally counted as Indian. Thus a couple of restrictions applicable to the FERA companies would now be applicable to only two companies. There has been a demand to put all the ex-FERA companies is a separate category and not to treat them on par with the rest of the Indian companies. But under Rajiv Gandhi's leadership, such a demand has not been accepted. Self-reliance is no more a serious slogan.

Increased Rates of Profit

Under the New Drug Policy, the drugs have been recategorised as category I and II. Category I would consist of those drugs which are required for various national health-programmes; and category II would consist of 'other essential has not been published. The whole aim of this exercise is to reduce the total number of drugs under price control. Only those drugs belonging to these two categories would be under price control. The prices of the rest would be 'monitored'; but they would be out of the price control basket. Going by the list prepared by the National Drugs and Pharmaceutical Development Council (NDPDC), three years back, this list of "essential drugs" would consist of around one hundred drugs, instead of the required number of around two hundred. Today, about 360 bulk drugs are under price control; the majority of these would now join the category of decontrolled drugs.

Even those which would continue to be under price control, would fetch a higher profit-rate than hitherto. According to the Drug Price Control Order (DPCO) of 1979, category I consisted of life-saving drugs which were allowed a 40 per cent 'mark-up;' category II consisted of 'essential but not life-saving' drugs with a permissible mark-up of 55 per cent and category III consisted of 'useful drugs, new drugs' with a 100 per cent mark-up. The rest, mainly consisting largely of quite useless drugs could earn unlimited profits. The NDP has now two categories with a "Maximum Allowable Post-manufacturing Expenses" (MAPE) a new term for 'mark-up'—prescribed as 75 per cent and 100 per cent respectively for these two categories. (Readers may note that 'mark-up' or MAPE includes manufacturer's profit plus costs and profits of transport, and sale.) This hike in mark-up would cause a price-rise in life-saving and other essential drugs in these two categories by 12 per cent to 25 per cent according to the government's own admission. Many essential drugs are not going to be included in these new categories I and II and hence would be decontrolled. Their prices would increase 'as much as the market can bear'. As a result the prices of essential drugs would rise much more than this official estimate. According to the Secretary of the Indian Medical Association, which is otherwise a conservative body, the drug prices would rise by 60 to 300 per cent.

Unnecessary Price-rise

Many of the leading national dailies have refrained from criticising head-on this increase in mark-up. Many of them have called it as a 'sensible' step. If one takes the arguments of the drug industry, uncritically, this step appears sensible indeed. But this increased mark-up and consequent price-rise in unjustified on three accounts:

a) The drug industry argues that the earlier mark-up of 40 per cent and 55 per cent was 'unremunerative' This assumes that the cost-price as given by the drug industry is not fictitious. The cost calculations furnished by the industry to the Bureau of Industrial Costs and Prices (BICP) are considered as trade-secrets and are not available for scrutiny by any other public body. Let these figures be published and be verified by other experts in the field. The study quoted by industry sources to show that the earlier mark-up was not remunerative was done by the National Council of Applied Economic Research (NCEAR) but was funded by the drug industry. Let there be an independent study by a public body to determine the real costs of manufacturing. It is only then the question whether the existing mark-up is genuinely inadequate can be meaningfully discussed.

b) It is true that the wholesaler stockist claims 8 per cent of the selling price as his commission and the retailer a minimum of 11 per cent. These selling costs are in addition to transport and sales-promotion costs. This leaves comparatively limited profits for the manufacturers when the mark-up is 40 per cent (i e, when the selling price is to be upto 40 per cent higher than the manufacturing costs. This calculation, it may be noted, assumes that the manufacturing costs have not been fictitiously jacked up.) If this is the situation, the real solution in order to increase manufacturing profits is to reduce the costs and profits of distribution and marketing. The wholesaler's margin should be reduced to 3 per cent as in the case of other sectors. Secondly, the promotional expenses can be drastically reduced. Giving free samples, gifts to doctors, dinners after 'scientific seminars', etc, etc, are huge social-wastes which need to be stopped. But the Indian state is not in a position today to control the profiteering of even a section of the commercial bourgeoisie (the stockists). That is their problem. The left should ask why should the people pay the price for the timidity of the Indian state? Similarly, high-promotional expenses are "necessary" for monopoly capitalism, but the left has to ask—" why should the people pay for these necessities of monopoly forms of competition'? In case of the MNCs, these promotional expenses were as much as 33 per cent of the costs as per the data collected by the Lovraj Kumar Committee.

c) Today drugs are costly because they are available mostly in the form of drug combinations. Most of these drug combinations consist of an essential drug and one or more unnecessary or useless or even harmful ingredients. For example, popular analgesic brands like Aspro, Anacin, Powerin etc, etc, consist of aspirin as the essential ingredient and in addition one or two unnecessary ingredients. The price of aspirin is 3 to 5 paise, whereas that of these irrational brands two to four times as much! AIDAN has, therefore, demanded that all such irrational drug combinations should be banned and that only rational, essential drugs be made available under generic names only. If there is a sufficiently strong movement which makes the government accept this demand, then prices of a overwhelming majority of drugs would be drastically reduced. (Prices of single-ingredient drugs will not be reduced much.) A rise in mark-up if, and to an extent genuinely necessary, can be allowed only if this above demand is accepted. In such a case, the price of aspirin would be increased by one or two paise but since there would no more be any costlier irrational brands (Aspro, Anacin etc.) available at all, the consumer's expenses on analgesics would still be much less. This demand of AIDAN has no been accepted by the government because the movement is not strong enough.

This demand is not a socialist demand in itself since it does not question the very existence of the capitalists in the drug industry. All it says is that "you earn a reasonable rate of profit by selling really useful drugs and not a lot of junk in addition." The World Health Organisation and other such

non-socialist bodies have also been advocating the sale of only rational, essential drugs under generic names. The problem is, the people's movement, the health movement is not strong enough today to force the government to discipline and control the parasitic, antiquated interests like those of the stockists, or the monopoly-interests in the drug industry. Though monopoly capital as a whole is in the dominant position in India, a control over their reckless profiteering *in one sector* is possible even within bourgeois bounds if the people's movement is strong enough. This has been achieved to a certain extent in Bangladesh due to the combination of public pressure, historical accident and populist initiative by the government. A similar thing can happen in India also.

Delicensing and Indigenisation

According to the industry, licensing means a lot of unnecessary beaurocratic interference (which also breeds corruption) with the "freedom of enterprise". But this is an antiquated, 19th century thinking. That "free-market economy" leads to repeated small and big crises which are too painful for the people and hence inconvenient to the capitalist class as a whole and therefore, capitalism needs to be regulated at least to a certain extent has been proved in theory and in practice over and over again the world over. It is true that some of the licensing procedures and other governmental regulations are too cumbersome today and they also create another parasitic layer of administrative beaurocracy which sometimes harasses the individual capitalists or other citizens for its own corrupt interests. Thus a regulatory mechanism which has evolved historically to smoothen to a certain extent, the anarchic function of capitalism is not doing its job properly.

The solution to this is not to abolish the regulatory mechanism itself; but to simplify it, to make it more efficient and functional. But under Rajiv Gandhi's leadership, there is not even a concern for overall planning in the interests of the capitalist class as whole. The new 'modern' policy-makers have been yielding in an *ad-hoc* manner to the purely sectional interests of the Indian and foreign monopolists or sometimes to the purely sectional interests of other sections of the capitalist class. This is at the expenses of the working-masses and also at the expense of the long-term interests of the Indian capitalist class as a whole. The policy of delicensing in the drug-industry by the Rajiv-regime is a case in point.

Before the announcement of the NDP, the Rajiv regime had delicensed 82 drugs which means any company can produce any of these 82 drugs to any extent without prior permission of the government. Now according to the NDP, this policy is to be 'progressively extended'. The reasons given for this policy are: to remove unnecessary hurdles in the way of the industry, so that there will be abundant production of those drugs which are in short-supply. But in reality the consequences would be quite different:

a) Many of the essential drugs have been in short-supply today not because of the licensing system (a few exceptions apart) but because they were under price-controls. The drug industry could get a much more higher rate of profit in the production of decontrolled drugs and hence it concentrated its efforts on the production of these high-profit though mostly useless drugs. Of the 94 drugs delicensed, 75 so far (even before the announcement of the NDP) have been open for all sectors for production. But the MNCs and big companies by and large neglected their production. In the NDP, except for about a hundred drugs, all the rest would have no price-controls and hence the drug industry would continue to neglect these 100-odd priority essential drugs and would continue to concentrate on the rest. The shortages of priority essential drugs would continue so long as the non-essential, useless, irrational drugs are allowed to be produced and moreover are allowed higher-profit rates.

In case of certain essential drugs the existing capacities are today underutilised because the drug-companies have not been interested in a 40 per cent or 55 per cent mark-up. But now that the mark-up on these drugs has been increased to 75 per cent and 100 per cent, the drug-companies may now fully use their existing capacities. In the short-run therefore, there may be increased production of some of the essential drugs. This should not be interpreted as "success of the delicensing policy". In the long run, newer capacities would be developed for the decontrolled drugs more than those for the priority essential drugs.

b) Whatever limited planning that exists in capitalism requires that the planning authorities can intervene to stop/reduce or encourage the production of certain drugs or to intervene to balance the growth of different types of companies in different areas. Delicensing would mean the drug production would be entirely left to the chaotic market forces. The government would not be able to do anything about it, nor would it be able to threaten the monopoly companies with the stick of the licensing authority if these companies indulge even in brazen malpractices to fleece the consumers.

Delicensing would not be applicable to FERA and MRTP companies. But now legally there would be only two FERA companies and only a couple of Indian drug companies would be counted as MRTP companies since now the limit for inclusion in the MRTP list has been raised to Rs 100 crore by the Rajiv-regime.

The deleterious impact of delicensing can be congertly visualised since 12 drugs in March, 1983 and 82 more in June, 1985 have already been delicensed. As a result, a number of monopoly companies have registered capacities for production of many delicensed drugs in quantities which are 3 to 10 times the targets for the seventh Five Year Plan! Generally, most of these capacities are not utilised by the MNCs. Registrations are made primarily to preempt competition! For example, Duphar Interfram had 39 registrations in 1980-81; but utilised only 18 of these; in 1984, it acquired eight registrations but used none of these. The government cannot do anything about the chaos thus produced.

The ex-FERA companies would now more easily push out other companies and this would, amongst other things, push up the import-content of drug-production in India. A study of production of 8 drugs by MNCs after delicensing has shown that the import of these drugs has increased substantially. For example, Boots produced 20 tonnes of Ibuprofen and imported 4 tonnes in 1980-81, whereas by 1984-85, the imports of this drug by Boots increased to 62 tonnes but indigenous production by Boots increased to only 51 tonnes.

Delicensing would, therefore, lead to a further control by

the monopolies over the Indian drug industry and a further chaos with all the ill-effects for the people as well as for the balanced development of the Indian capitalist class as a whole.

Probably in order to stave off criticism on the forecasted increased import of drugs due to further delicensing the government has announced in the NDP, a scheme if 'indigenisation'. The NDP lays down that in cases where the import content of a product is more than 20 per cent, the drug companies would be required to submit an annual plan of how its production is going to be indigenised. This is a very loose formulation. Suppose, a foreign company unnecessarily imports, say codene, and prepares a costly, irrational cough mixture by adding a number of unnecessary ingredients to it so much so that the imported essential ingredient comes to less than 20 per cent of the total cost then, this new restriction of 'indigenisation' would not be applicable to this product. Thus vital, essential ingredients can continue to be imported in large guantities. Secondly, there is no time-limit given for 'indigenisation' nor any punishment specified if the companies do not observe in practice the plan of 'indigenisation'.

What is in fact needed, and is technically, definitely possible, given the developed technical capacity of the drug-industry in India, is more or less a complete indigenisation in say three-five years and rapid, drastic reduction in the current rising drug-imports (Rs 198 crore in 1984-85!) Sudip Chaudhury (see references) amongst others, in his detailed study, has shown that this is technically very much possible. The Indian state, because of its class-character is not able to take this step even today. On the contrary, during the last five-six years (even before the Rajiv regime), it has been forced to give more and more leeway to MNCs. The NDP is yet another example that Rajiv Gandhi's leadership has considerably accelerated this proces.

Broad banding

This is another measure to "remove the unnecessary hurdles in the growth of the industry." Broad-banding means that if a drug-company gets a permission for the production of penicillin, then now it can produce all types of penicillins and chemically related analogues like ampicillins and the like. The companies would not be required to take separate permission from the drug controller for a new formulation once the basic type has been allowed. If such broad-banding is done for single-ingredient bulk drug only, then it is a sensible step within the chaotic capitalist economy because companies can produce in the same plant, chemically related products in changing quantities depending upon orders they receive without asking for a licence each and every time. This can enable them to fully utilise the production-capacities they have built.

But the NDP allows broad-banding of formulations also. This means that if a company has a licence to produce a mixture of say three types of analgesics or vitamins, it can change their proportion or change a bit the chemical structure of one or more of its ingredients and sell the 'new' product under a new brand name. Earlier, the companies had, at least, to undergo the formality of applying and getting a permission. Now there will be a totally uncontrolled growth of all sorts of irrational drug-combinations sold under a range of newer brand-names. It would become more or less impossible to monitor the prices of the new formulations in order to check price-rise. Monitoring the quality of drugs would also be a mammoth task for the government since it is impossible to check the ingredients qualitatively and quantitatively if we have over 50-60,000 formulations.

Quality Control

The NDP seeks to make Good Manufacturing Practices a statutory requirement. This was quite an overdue step. But the problem is, there is no mention of qualitatively improving and strengthening the existing too weak, too ineffective and corrupt drug-regulatory authority. The statutory requirements would, therefore, remain on paper.

The NDP is to make a compulsory certification system for quality-control from 'recognised institutions'. This means, now there will be specified institutions for this purpose. Whether such institutions would be private or public has not been mentioned. Going by the Rajiv regime's trend towards privatisation, it is likely that privatisation will take place here also. The data with private laboratories is considered trade-secrets and generally it is impossible to get these data to find out whether a particular private company has been doing its job honestly or whether like the notorious Chemical Labs involved in the JJ Hospital death-scandal, the private laboratory is giving false reports. Though many public authorities tend to be as secretive, public laboratories can be more accountable with increased public pressure. In case of private laboratories, it is their constitutional bourgeois right to keep their trade-secrets confidential.

The government does not want to spend money on increasing the number of public laboratories upto the required number whereas it is willing to squander money on all types of useless or anti-people projects. Hence the move towards privatisation. This must be stoutly opposed. At the same time, as a measure of rational utilisation of existing resources, public bodies like laboratories in research-institutions, universities, etc, can be entrusted to a certain extent, this task by fortifying these facility-centres with the needed extra equipments and personnel. This would obviate to a certain extent the need to build new facility-centres from scratch. Whether the existing system can do this is a moot point even if socially, it is quite a viable propositon.

Medical Issues

Health and science groups in India have identified the following key-issues from a medical aspect as part of a rational drug policy; none of which find a place in the NDP.

i) Preparation of a priority essential drug-list and a comprehensive rational drug list for India. Production of drugs to take place in accordance with only these lists and no other.

ii) To assess quantitatively the drug needs of the Indian people on the basis of a study of prevalence of the disease-pattern in the country and to plan the production accordingly.

iii) To completely and immediately ban all the irrational and hazardous drugs. Only drugs as specified in (i) to be allowed.

iv) Complete abolition of brand-names and replacing them

with generic names, with the company's name in the brackets; for example, "Penicillin-V (Alembic)".

v) Stopping the 'disinformation' of doctors and consumers by drug companies. Continous compulsory reeducation of doctors and relevant education of consumers by state medical authorities.

vi) Strict check on the unethical marketing practices by the drug companies; a ban on incentive-schemes and on giving samples and gifts to doctors by drug companies.

vii) Adequate supply of drugs free of charge to poor people through the government set up. Rational utilisation of the existing budget and increasing it rapidly to the adequate level.

vii) To stop the continuing colonial heritage of step-motherly treatment being given to the non-allopathic systems of medicine; to encourage research in these systems with financial and other support. At the same time to disallow the commercial production of any drug by any company unless it is accepted as scientifically proved (effective and safe) by appropriate bodies. Encouragement to ayurveda does not meant that Richardson-Hindustan be allowed to avoid taxation or to get other concessions by naming its Vicks Vaporub as herbal medicine! To enact that medical practitioners would use only those medicines or therapies in which they have been adequately trained by recognised institutions.

The NDP talks about only the standardisation of non-allopathic drugs and preparation of standard formulary for non-allopathic systems of medicine. There is no serious research policy nor any attempt to curb production of irrational (may be hazardous also) medicines under the name of ayurveda of the misuse of these medicines.

ix) All medical research on human beings must be statutorily required to confirm to the 1975 Helsinki (Mark II) Declaration. This should be strictly followed in case of contraceptive research also.

None of these medical demands have been accepted. One may conclude that the NDP is only a pricing and 'liberalisation policy' with no concern for rationalty or people's health needs. The foregoing account shows that as an industrial policy also, it is clearly reactionary and anti-people.

Economic and Political Weekly

A journal of current affairs, economics and other social sciences

Every week it brings you incisive and independent comments and reports on current problems plus a number of well-researched, scholarly articles on all aspects of social science including health and medicine, environment, science and technology, etc.

Some recent articles:

Mortality Toll of Cities—Emerging Pattern of Disease in Bombay: Radhika Ramsubban and Nigel Crook

Famine, Epidemics and Mortality in India—A Reappraisal of the Democraphic Crisis of 1976-78: Ronald Lardinois

Malnutrition of Rural Children and Sex Bias: Amartya Sen and Sunil Sengupta

Family Planning and the Emergency—An Unanticipated Consequence: Alaka M Basu

Ecological Crisis and Ecological Movements: A Bourgeois Deviation?: Ramachandra Guha

Environment Conflict and Public Interest Science: Vandana Shiva and J Bandhyopadhyay

Geography of Secular Change in Sex Ratio in 1981: Ilina Sen

Occupational Health Hazards at Indian Rare Earths Plant: T V Padmanabhan

Inland Subscription Rates

Institutions/Companies one year Rs 250, Two years Rs 475, Three years Rs 700

Individuals Only One year Rs 200, Two years Rs 375, Three years Rs 550

Concessional Rates (One year): Students Rs 100; Teachers and Researchers Rs 150

(Please enclose certificate from relevant academic institution)

A cyclostyled list of selected articles in EPW on health and related subjects is available on request.

Medical Officers—The 'New Middle Class'?

I WAS a little bit surprised by Sujit Das's rather sharp response (Organising doctors: a difference in approach, *RJH*, Vol I:2) to my critical comments (*SHR*, Vol II:3) on his article and my separate piece on 'Organising Doctors' in the same issue.

Das feels that my remark that his article is a "shamefaced defence of the interests of the doctors" is a rude one. The dictionary-meaning of "shamefaced" is "bashful, shy, retiring, modest. . ." and has no rude connotations.

I am not sure whether I should go into a detailed debate about the questions of terminology raised in the second paragraph of his response. Some people including Das may find it irrelevant. I would only point out that a mode of production is a relatively stable set of relationship consisting of a specific intertwining of productive forces and production relations and which reproduces itself over and over again. Petty-commodity relations by their very nature cannot constitute a mode of production (a stable, self-reproducing mode) but must disintegrate over a period of time; general practitioners would, over a period of time, more and more be replaced by hospital-owners-capitalist doctors on the one hand, and the wage-earning doctors on the other hand.

Now about the central issues: The main difference in approach according to Das is:-

1) "Phadke wants to organise doctors towards the end of fulfilling the tasks set by his own lofty ideal" Das, however, believes that "such idealistic approaches have never helped".

I plead guilty to his first charge; I would only hasten to add that the "lofty ideal" is not my personal invention. All those who believe in scientific socialism from the point of view of human liberation believe in a "lofty ideal" of a revolutinary charge. His second charge is however, a little off the mark. I have not taken any idealist approach. I have started with a "materialist analysis of position of doctors", and have then tried to point out the contradictory class-location of medical officers—medical officers being one important layer within the category of wage-earning doctors. Based on this materialist dialectical analysis, I have questioned the existing strategy of organising this new middle class "*mainly* on the basis of their trade-union demands" (emphasis added).

2) Das disagrees with my critical attitude towards doctors: It is, of course, true that a socialist health system cannot be run without doctors. But it is also true that a revolutionary socialist transformation in the medical system cannot be *initiated* by a new middle class organised mainly on trade union demands. Such a change can only come (as a part of a broader revolutionary transformation) through revolutionary coalition within and outside the health system in which medical officers as a *social layer* may or may not participate. It should be the attempt of marxists to bring at least a section of this new middle class to the side of the revolutionary programme; and my contention is that this cannot be done by organising them mainly on their trade union demands. Upholding the interests of medical officers as wage-earning health-workers is not enough. Scientific socialists have to be critical about their interests as officers. There has to be an independent platform clamouring for a revolutionary-change in the 'health-system'. Such a platform will take a dialectical approach to the contradictory interests of medical officers. It is not necessary that the majority of the new middle-class comes to the side of the revolutionary programme. There is a more numerous other section of doctors (junior doctors) and much more numerous paramedics who are more likely to come to the side of a revolutionary programme in the field of health. Those medical officers who do not join such a platform today will have to accept and implement after the revolution, the programme chalked out by this platform. Das, however, disagrees basically with my characterisation of the medical officers as part of the new middle class. For two reasons—the first reason is rooted in his misunderstanding of the concept of the new middle class. I have explained my understanding of this term at some length in my note '(Organising Doctors; Towards What End?)' and it should be clear to anyone that I have not 'adopted this formulation' of identifying "the highly skilled wage-earners of advanced capitalist society as new middle class." For me, their position as new middle class is not due to their "skills" but derives from their role as officers. Das's second reason is that "by no stretch of imagination could India be labelled as an advanced capitalist society;" and the new middle class is a product of advanced capitalist society. India is, of course, not an advanced capitalist society like the West, but yet we have monopolists like Tatas and Birlas. In certain sectors, we do have signs of advanced, monopoly interests; and the new middle class (executive engineers, foremen, supervisors, medical officers all those who perform the function of the labourer as well as that of capital as officers) is very much a reality in India.

3) Das disagrees with me on empirical grounds also. ("I have not found these doctors, as a class, performing the function of capital, of supervising, extracting work from the paramedics. . .") The problem is tht Das continues to talk about "doctors in service" as a homogenous category,

whereas I have distinguished between doctors with hardly any administratively supervisory or executive function, e g, the junior doctors on the one hand, and the medical officers who have to perform these functions on the other. If one goes to any Primary Health Centre, one would immediately come across a series of executive, supervisory tasks over the work of the paramedics that the medical officer has to do. It is because of their status as 'officer' that the MOs at PHC get well-built quarters or bungalows (though no such accommodation has been built in many new PHCs;) whereas the junior doctors share one room amongst 2-4 doctors. The MOs get a salary which is higher compared to that of the junior doctors though junior doctors are many a times clinically more competent and are more overloaded with work. The MOs can be compared with the parademics also. The salary and the facilities that the medical officers have, are more than would be explained purely by their training if we compare them with the paramedics (like the ANMs). It is because of their dominant position as officers that many medical officers illegally earn money with impunity through private practice. Medical officers *as wage-earners* have many problems and that is why they have been unionising. But marxists, scientific socialists should not point out only to their problems but also must bear in mind their status as officers.

Contrary to Das's assertion, I have not 'discounted trade unionism as such', nor have I said that doctors should behave as if the world around is not commercial. I only wanted to point out the fact that Das has not given any class-characterisation of doctors though the title of his article raises this expectation and though he raised this question in the text also. Instead, the article gives an account of the problems faced by the doctors without looking at their contradictions and hence becomes a kind of a one-sided defence of the interests of doctors.

—ARS

(*Continued from page 77*)

responsibilities to serve the needs of the dominant class. Total state control is a hightened level in the process of socialisation. On the other hand, at the present moment it is obvious that total state control is not equivalent to people's control. Our conception of people's state or proletarian state has received a jolt from the experience of the socialist countries. People's participation also remain elusive without sharing in power. A rethinking is perhaps in order to conceptualise people's control in political and organisational terms.

But then it is also on observable fact that total state control or major state control, in whatever form, have brought about more equitable distribution of health care among the people. Its contribution in human values has proved to be immense.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or Marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication which means that the issue on Primary Health Care is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated, author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (for issues). I am sending Rs._____ as subscription and/or donation, by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

"When one individual inflicts bodily injury upon another, such injury that death results, we call the deed manslaughter; when the assailant knew in advance that the injury would be fatal, we call his deed murder. But when society places hundreds of proletarians in such a position that they inevitably meet a too early and an unnatural death, one which is quite as much a death by violence as that by the sword or bullet; when it deprives thousands of the necessaries of life, places them under conditions in which they *cannot* live—forces them through the strong arm of the law, to remain in such conditions until that death ensues which is the inevitable consequence—knows that these thousands of victims must perish, and yet permits these conditions to remain, its deed is murder just as surely as the deed of the single individual; disguised, malicious murder, murder against which none can defend himself, which does not seem that it is, because no man sees the murderer, because the death of the victim seems a natural one, since the offence is more one of ommission than of commission. But murder it remains."

Nightmare of a Dream

ON DECEMBER 2, 1942 the first nuclear reactor went critical, releasing for the first time the enormous energies of atomic fission and ushering in the nuclear dream. But the reality was to be different; the dream rapidly turned into a nightmare. By the end of that decade not only had energy from the atom claimed 'war victims' but it had also shown its potential in killing, maiming and scarring for life anyone who worked with it. As early as August 19 a young worker at the Los Alamos 'atom bomb laboratory' working on fission studies died an agonising death after accidental exposure to radiation even as his numerous colleagues transporting fission material or experimenting with it were becoming permanently affected. By the fifties while several countries had built commercial reactors producing electricity, well-developed weapons programmes were also under way. And that was when the myth of the peaceful atom took shape and gained substance.

The nuclear debate, in addition to being a human rights issue directly impinges on all aspects of health care. A nuclear war, even a limited one, would be completely unmanageable by even the most efficient and most sophisticated health care system. (See p 112) Moreover no weapons system, even if meant as a deterrance, and however rudimentary/skelatal can be built up without some kind of testing of the devices. This has a direct consequence for the burden of ill-health among people not only of the affected region, but globally. And then there is the expenditure on armaments which is eating into the already meagre health and welfare budgets. While this is true of all countries, it has a more disastrous impact on poor nations. The 'peaceful atom' too is a health hazard. Three Mile Islands and Chernobyls can with the increasing proliferation of nuclear reactors, happen more frequently. With the secrecy which is an integral feature of the international nuclear industry, we may not even know when and if such disasters have taken place. Besides, evidence is accumulating on the long-term effects of low-level radiation, once thought to be 'harmless'. (See p 113)

'Atoms For Peace'

It is not an accident of history that the Atoms for Peace programme was proposed by Eisenhower in 1953. By then the military expenditure on nuclear installations had overshot anything that the country had spent even during times of war; the anti-bomb lobby while certainly not influential enough to change the course of development, at least had nuisance value; nuclear reactors whether for peaceful uses or for war weapons development were essentially the same; under US legislations weapons technology could not be shared with non-weapons countries—an important political lever for other kinds of gains in international diplomacy; it was only logical therefore to devise ways and means of continuing and expanding research and development efforts in nuclear sciences which while being ostensibly 'civilian' could easily be harnessed to war efforts when needed.

Thus the technical linkages between peaceful and military nuclear reactors—i e, the fact that it is during the process of controlled fission that the bomb material is produced or that the enrichment plants used to produce fuel for the 'peaceful' nuclear reactor can also, with sufficient modifications, be used to manufacture bomb material—have been politically reinforced. To argue that the two, the peaceful atom and the military atom are different is neither politically nor technically tenable.

It is in this context that the Indian nuclear programme got under way. It would be incredibly naive today to believe that the Indian bourgeoisie at the time of independence were not aware of the weapons potential of the peaceful nuclear programme. The fact that the programme has from the beginning been accorded high priority in terms of funding, that it has always been under the prime minister's direct control, the creation of the Atomic Energy Act with its unbelievable powers to suppress information, and the fact that the department's accounts have never been open to public or parliamentary scrutiny or audit by the Auditor General of India are obvious indications that the weapons angle has always been kept in perspective in developing the programme. Events in subsequent years especially in the last decade have given further evidence of this.

The nuclear debate is not new. While the dissent of the 50s was generally focussed on nuclear armament, the first ever protest against a nuclear power reactor was organised in 1957 in the US. But it is in the seventies that the nuclear debate came into its own. Throughout the 60s even as more and more 'peaceful' nuclear reactors were being built, data was also accumulating about radiation-related deaths among victims exposed to nuclear test fallouts, about the numerous things that could go wrong in a nuclear reactor, and about the potential long-term effects of low-level radiation.

Throughout the fifties the US continued to test nuclear weapons in a variety of geographical locations—66 of the 200, were in the Pacific ocean. While radiation damage from the fallout had been accumulating slowly over the years throughout the area, it was the Rongelap or the Bikini test which brought home to the world not only the horrors of the nuclear armaments programme even during peace time, but also the horrendous coverup used by the US and every other state which has had anything to do with the

atom—the denials, the coverups and the secrecy. Children of Rongelap played in the 'snow' from the massive fallout from the test which entirely covered the ground for 78 hours before the US decided to inform the islanders of the deadly radiation and evacuated them. The first five years saw a sharp rise in miscarriages and stillbirths; but it was only after 9 years that the US medical experts acknowledged that the children were particularly prone to thyroid problems and the seriousness was highlighted when a 19-year-old boy who had been the youngest to play in the 'snow' died of leukaemia. Women from Rongelap continue to give birth to what they describe as "a bunch of grapes"—a consequence of radiation exposure because of which cystic grape like structures occur in the uterus or sometimes a single hydatiform mole is formed from a fertilised ovum which has lost its nucleus.

The peaceful atom too was beginning to show its belligerence—the increasing health problems of nuclear workers—the uranium miners, the transporters, reactor operators and the whole army of workers—was forcing several nations to pass legislations. But this also led to successful efforts to formulate so-called safety standards which only obliterated the real effects of radiation damage.

It is interesting here to point out that the international bodies which are supposed to set the limits of exposure and monitor it are themselves open to criticism of bias. Moreover, even as evidence accumulates about the extensive and long-term damage due to nuclear operations, the levels of exposure etc have been revised and concepts modified to accommodate them. For instance, it is now accepted that there is no safe dose of radiation; therefore the 'permissible dose' was evolved. And ironically enough it is not the health establishment which has traditionally been involved with monitoring these aspects; the discipline called health physics which evolved at around the time of the first nuclear reactor has been dominated by physicists and engineers and its fundamental concern has been to give the nuclear industry a clean chit. (See page 119 for discussions on the biases in concepts of 'risk' and safety'.)

Anti Nuke Debate

It is pertinent to ask why a debate which has been going on for over three decades needs to be given space and attention here. There have been several developments in the past few years about which we can neither remain unaware nor unconcerned. For one thing after four decades of the arms race the US and the USSR are on the verge of reaching a historic agreement on dismantling nuclear weapons in Europe. If the agreement on dismantling intermediate range missiles in Europe whatever its limited scope comes through it will be the first ever of its kind. Undoubtedly, national and global economic and political considerations have had a lot to do with the move, with the growing European peace movement, which is itself another manifestation of these considrations, providing a motive force. The growth of the peace movement cannot be measured only in terms of numbers but in terms of its political effectivity. One consequence of this has been the incorporation of many of the anti-nuke movements, demands into the programmes and manifestos of opposition parties in Europe. While the Green party has gained ground in West Germany in the last election, in Australia and Iceland too parties with a major focus on anti-nuke and peace issues have contested elections and won parliamentary representation. The communists in France are actively participating in anti-nuke demonstrations, for the country has continued to conduct nuclear tests in the Pacific despite worldwide protest. At Greenham Common, UK women have been camping outside the defence area in protest aganst the deployment of Cruise missiles.

In the Pacific too, several nations have come together to declare the zone a nuclear free one with many countries, including the USSR and excluding the US ratifying the declaration. Not the least of these new developments has been the spectacular impact of the International Physicians for the prevention of nuclear war (IPPNW) (See p 111)

But closer home a vocal nuclear lobby is pressurising the Indian state into giving the final signal to produce the bomb which is supposedly all but ready. Moreover the nuclear industry is planning the biggest expansion programmes, with a target of 10,000 MW of power from nuclear sources. Capitalist development in India poised to shift gears to a more rapid growth which will inevitably make demands for changes in the economy. The atoms-for-progress-and-peace theme is acquiring new meaning. Acquiring nuclear weapons capability not only becomes necessary as deterrance 'to keep peace' in the region, but also to reassert hegemonic aspirations. At the same time nuclear power with its long-term advantage of low labour inputs, centralised control etc is seen as the only means of providing for the power requirements of industrial growth.

Thus the nuclear debate has both a global and a national dimension and within this broad perspective are several issues. There is on the one hand the issue of how we view war, nuclear armament and disarmament at the global level as well as the national. Recent marxist analyses of war see it mainly as a condition of capitalist production. They argue that highly industrialised capitalist economies generate surplus value at such a rate that capital begins to accumulate rapidly and this inevitably leads to falling returns of investment thus leading to crisis. The creation of defence establishments which must be kept ready to strike at all times in terms of training, competence and technical superiority provides for vast capital expenditures in a justifiably non-productive fashion—ie without creating new value. Seen in this light the theory of deterrance, whether it is in terms of keeping huge conventional military establishments or building up nuclear armaments and deploying them becomes a conditions

of capitalist production.

In the context of international capitalist development it is absurd to take one view of war and armament on the global level, i e, support disarmament efforts, while at the same time take a completely different view at the national level, i e, support the bomb lobby encouraging nuclear arms production.

Equally, it would be utterly naive and blind to try to delink the nuclear arms issue from that of nuclear power. Setting up a nuclear capability for producing 10,000 MW power is equivalent to establishing the base for producing a full complement of nuclear weaponry. But for the moment let us assume that it is possible for us to seperate the two. Would nuclear power be a feasible and safe proposition then?

It is important here to point out that India has been active on the peaceful nuclear front at every level of the nuclear cycle. Uranium is mined in the country; this ore as well as other fission materials can be processed and enriched, albeit to a limited extent according to official sources; we have several reactors which even if they have never been working efficiently to produce power for which they were ostensibly set up they have been producing fission products in large quantities and huge quantities of radioactive waste; India has had a sophisticated reprocessing facility for almost as long as it has had its first power reactor and it has had to store the long and short half life wastes in many dumps.

There is today enough information worldwide to show how workers and "non-workers in and around these various nuclear establishments are being permanently affected by radiation damage. Indian studies (see p 124) have shown just how incapable the department has been in monitoring the health of workers in the Rare Earths plant at Alwaye in Kerala one of the oldest such plants in the country. Since the 70s several stories of how workers are exposed to high radiation doses during cleanups have reapetedly surfaced from Tarapur and Rajasthan. The department has kept on record of people around any nuclear installations; but recent studies in UK have shown a definite possibility of childhood leukaemia clusters around power plants and no significant contraditions have as yet come forth despite close scrutiny of the studues. And nobody is aware of where the nuclear waste dumps are which is classified information under the Atomic energy Act Government control.

In fact the Act which vests extraordinary powers with the state is perhaps the most draconian of legislations in the country. It permits the nuclear industry to get away with criminal negligence of the most basic safety norms. And yet quite amazingly, it has, by and large escaped criticism—the Parliamentary opposition has never made an issue of demanding a review of the Act.

And then there are two other issues—one of the possibility of accident at a nuclear facility and the other of 'retiring' old plants. It is clear now that Three Mile Island and Chernobyl, the two publicly known nuclear accidents are not specific and rare instances—they can occur at any point in the nuclear cycle, no matter how fail-safe the process. The secrecy which is part of any nuclear establishment anywhere in the world makes it impossible to ensure the safety of populations around. Only in the last decade has the issue of what to do with old nuclear plants received attention. The dilemma is that firstly, the expenses involved in shutting down are enormous, secondly a nuclear plant unlike other establishments cannot simply be abandoned it is in the nature of a time bomb because it will be radioactively 'hot' for a long-time and has therefore to be safeguarded and thirdly in the bright dawn of the nuclear era nobody had thought to make provisions, costwise or otherwise about dismantling these monsters.

But notwithstanding all this there is yet another facet of the picture which demands attention. Atomic energy has not only produced electricty but a variety of nuclear products used in a range of applications, particularly in medicine. There can be no denying the fact that the use of radioisotopes have enormously benefitted biomedical and engineering sciences and there is no substitute for radiation therapy with all its drawbacks and problems. While it is true that the technology to produce them may be different, can it not be argued that this is in many senses a matter of scale? Can we seperate this from the rest of the issue and would it be possible to confine all future applications, research etc only to these areas. Can scientific developments no matter what their impetus and the predetermined boundaries of growth, be entirely contained?

The Indian anti-nuke movement has been of fairly recent origin—but it has already made considerable impact on an establishment, which for the first time has been forced to give serious consideration to sensitive questions. But the medical establishment, has in keeping with its class interest kept out of the picture.

However, if health is our everyday concern and if we believe that health care in more than medicare and is a political issue, we have to confront the nuclear issue. For, in doing so, we confront in quintessence, the contradictions and consequences of world capitalism.

Medical Response to Nuclear Threat

IN 1961, a group of young physicians from Boston founded an organisation called Physicians for Social Responsibility (PSR). Among them were Bernard Lown, Jack Geiger, Victor Sidel and Sidney Alexander. Beginning with an historic article in the *New England Journal of Medicine,* they calculated and publicised the medical consequences of a nuclear weapon detonated over a major city.

After a period of dormancy, PSR was revived in 1978 by another group of young Boston doctors, including Helen Caldicott, Eric Chivian and Ira Helfand. The organisation was concerned with both nuclear weapons and nuclear power, and developed a national constituency in the wake of the accident at the Three Mile Island nuclear reactor in Pennsylvania. In the following year, PSR decided to focus its attention on the nuclear arsenals. Dr. Chivan, a psychiatrist at the Massachusetts Institute of Technology and Harvard Medical School, agreed to design and organise the first major American conference on the medical consequences of nuclear war.

At the same time, Dr. Lown and several other American physicians, including Harvard Medical School professors Dr. James Muller and Dr. Herbert Abrams, began discussing the possibility of a Soviet-American medical dialogue on nuclear war. Dr. Muller had studied cardiology in the Soviet Union and later visited there on official delegations. He and Dr. Lown agreed there should be some kind of joint effort by Soviet and American physicians to address the nuclear arms race. Together with Dr. Abrams, chairman of the radiology department at Harvard, they formulated a strategy for approaching Soviet colleagues.

One key element of that strategy was the personal and professional relationship between Dr. Lown, a professor of cardiology at the Harvard School of Public Health, and Dr. Evgueni Chazov, director of the USSR Cardiological Institute. The two had first met in 1966.

Late in 1979 and early in 1980, Dr. Lown wrote to Dr. Chazov with a proposal to create a Soviet-American physicians' movement to prevent nuclear war. The proposal reasoned that doctors owe a professional duty to address the greatest threat to human life, and that an East-West medical organisation would be particularly effective in alerting the public and persuading governments.

In April 1980, Dr. Lown travelled to Moscow to ask Dr. Chazov to urge his Soviet colleagues to join such an effort. Dr. Chazov was encouraging, and in the spring of 1980, Dr. Lown, Dr. Abrams, Dr. Muller and Dr. Chivian incorporated IPPNW as a non-profit, educational organisation.

The efforts of the Boston physicians led to a meeting in December 1980 in Geneva between three American doctors and three to lay the international foundations of IPPNW.

Soon after, a small group of US physicians assumed the task of transforming the concept of IPPNW into an organisatioal reality. Their initial assignment was to organise the First World Congress of IPPNW. The Congress, held near Washington D.C. in March 1981, attracted 70 doctors from twelve countries.

In the eyes of the western press, the dramatic news from the First Congress was the presence of the Soviet delegation. When Soviet doctors joined their American, European, and Japanese colleagues in calling upon Presidents Reagan and Brezhnev to preclude the use of nuclear weapons "in any form or on any scale", the Congress achieved a major goal of the IPPNW founders—demonstrating to the world that American and Soviet physicians could co-operate on the gravest public health question of the time. This fact was under-scored by the widespread coverage given the Congress by Soviet press and television.

Soon after the First Congress, the American Medical Association, after reviewing material submitted by IPPNW and its US affiliate, Physicians for Social Responsibility, passed a resolution which recognised the professional obligation of doctors to educate their patients on the medical effects of nuclear war. The basic message of IPPNW's founders had entered the mainstream.

[Central Office: IPPNW, 225 Longwood Avenue, Boston, Mass 02115, USA.]

We Apologise

For Irregularity and Delays in Bringing out RJH

The reasons have been mainly technical and financial. But we are generally out of the woods and would be much more confident if we are assured of your continued support! So please do renew your subscriptions.

We will be bringing out the next issue, the first of the new volume in the next 45 days, at the latest. The focus of the number is 'Medical Technology and Health' and we're sure it will raise a number of issues for debate. Do make sure you get your copies. After that we hope to be back on schedule with: Drugs and Pharmaceuticals; Health in People's Movements; Health and Agricultural Development.

Financially, the Socialist Health Review Trust is collecting a corpus fund so that RJH can be supported. This fund is being collected through individual and institutional donations and donors may avail of tax benefits under the ATG scheme. Apart from this RJH is seeking life subscriptions of Rs 500 from individuals and Rs 750 from institutions. This will form a corpus fund which will support the publication from the interest earned. We aim to collect a minimum of 100 life subscriptions by the end of the year and we have quite away to go as yet. We would really appreciate your support/help in reaching the target.

One of the major objectives of the journal was to bring to readers material, opinion, debate and analyses, not easily accessible to activists and which would enrich and enlarge the marxist understanding of health. We believe the RJH has made significant contribution in the area and will continue to do so. We collectively recognise the political necessity of such an endeavour. No matter what the odds, RJH will continue to be published. We appeal to you to help us in whatever way you can.

RJH Collective

Anatomy of Nuclear War

achin vanaik

The date August 6, 1945. The Place - Hiroshima, Japan.

"NO one could understand what had happened. Thousands began to flee the city. Most of them seemed to be hurt or mained. Eyebrows were *burned* off, skin was hanging from faces and hands. were vomiting. Almost all had their heads bowed, looking straight ahead, were silent and shared no expression whatsoever. In general, survivors that day assisted only their relatives or immediate neighbours, for they could not comprehend or tolerate a wider circle of misery.

Towards evening the streets became quieter; "Now not many people walked in the streets but a great number sat and lay on the pavement, vomited, waited for death and died." Even now there was no organised help masses were dead, masses were dying. "They all felt terribly thirsty and they drank from the river. At once they were nauseated and began vomiting and they notched the whole day." There were a few people who were capable of helping others. Survivors that evening noted that the asphalt on the streets was still too hot to walk on with comfort. Two men noticed "a pumpkin was roasted on the vine", which was eaten. Potatoes under the ground were found to be baked and were gathered for food. Many desperately ill survivors found their way to the sand pits on the river deltas. The tide was coming in. Many were too weak to move themselves but were helped by exhausted survivors. "He reached down and took a woman by the hands, but her skin slipped off in huge glov-like pieces." Others were moved up the sand pit but the following morning they had gone as the tide had came higher than expected.

During the first day, Father Kleinsorge was asked to help some soldiers. "When he had penetrated the bushes, he was there were about 70 men and they were all in exactly the same nightmarish state; their faces were wholly burned, their eye sockets were hollow, the fluid from their melted eyes and run down their cheeks. This was the result of having their faces upturned when the bomb exploded." (Based on the book *Hiroshima* by John Hersey).

Not long afterwards during the Korean War, the American Pentagon devised what it called the 'Hiroshima Death Function' (HDF) to calculate what would be the effect of using nuclear weapons in a selective manner. This HDF was an algorithm to calculate mortality as a function of distance from ground zero of an airburst nuclear explosion. The HDF is

$$D(r) = 0.93 \text{ Exp } -\{0.693 \quad [(r - 800)/850]^2\}$$

where D = Deaths and r = slant distance in yards from point of burst for r greater than 800.

Despite the evil of nuclear weapons and the widespread revulsion at what happened in Hiroshima and Nagasaki, the contingent use of nuclear weapons has never been far away from the minds of nuclear warmongers. Certainly, these warmongers have few doctors or medical practioners in their ranks. Most of them are defence personnel, politicians, strategists, academics and so on. But how many medical practioners are aware of what a nuclear war means? And how many are actively opposed to such a war breaking out and to the nuclear weapons powers or potential nuclear weapons powers army themselves with such weapons?

Today, with the "live" experience of Hiroshima and Nagasaki a great deal is known about the medical consequences of a nuclear attack. A nuclear bomb explosion involves blast effects, heat effects, and the effects of ironising radiation. The proportions of these effects can vary depending on the size and nature of the bomb. For example, in the neutron bomb (the 'capitalist' bomb which kills people but does not damage property) the blast and heat effects are greatly minimised while the radiation effect is greatly enhanced. But in the 'normal' nuclear explosion, some 50 per cent of the energy goes as shock waves or other blast effects, 35 per cent as heat and 15 per cent as radiation. The range of these effects will be different if the bomb bursts in the air blast and heat range will be greater) than if it bursts on the ground (radioactive deaths, fall out etc, will be greater) or whether it explodes underground or underwater.

A sufficiently high overpressure (blast effect) on the human body will lead to rupture and haemorrhages in the lungs, air embolism and rupture of the gut and ear drums. In addition blast effects on buildings etc, will indirectly create many more human casualities through flying projectiles and falling debris etc.

The fireball of a nuclear explosion (small one) will look brighter than the sun at noon to anyone within a 50-mile radius of the explosion. To anyone looking at the fireball there is great likelihood of retinal burns leading to permanent blindness. The intense heat of such a fireball will raise flash burns of the skin. A partial thickness burn leads to blistering which can became infected. A full thickness burn is where the skin is completely destroyed. In both cases loss of crucial body fluids through the surface of the burn can lead to death. In addition, the explosion will create fires on the ground leading to flame burns which will cause lung damage through inhalation of smoke from a variety of burning materials especially plastic.

After a nuclear explosion comes the radioactive fallout as radioactive isotopes condense on debris and dust to produce the radioactive dustcloud. In the first 24 hours some 60 per cent of radioactive products fall to the ground. This is the early fallout. The 40 per cent which remains can take much longer to fall and can be dispersed over a wide area depending on weather, winds etc. This is the delayed fallout. This radiation causes damage to rapidly dividing cells such as those of bone narrow and the lining of the gastrointestinal tract. When the whole body is exposed one can get radiation sickness which is often fatal. One unit of dose i.e. energy absorbed per unit mass is called a rad and a dose of 450 rads will kill 50 per cent of young, fit adults. A dose of 150 rads will kill 50 per cent of elderly, already ill and children

In the first form of radiation sickness/the bone-marrow

form requires only an exposure of 150 rads. The first symptoms are lethargy and nausea, then nothing for 10 days. Towards the end of the second week there is maximum depression of the white blood cells and platelets which reduces the blood's capacity to clot and stop bleeding or protect against infection. Spontaneous haemorrhages often develop. By the fourth week many of the victims will die.

If the radiation exposure is high enough then there will be gastrointestinal damage where the cells of the small intestine are damaged. This leads to massive diarrhoea with loss of body fluids, to greater risk of getting septicaemia from bacteria emerging through the damaged living. If exposure is higher still, then the central nervous system of the body is damaged leading to convulsions, coma and death in a few hours. If the victim survives, there will be gradual loss of mental and physical faculties which then results in death in a few days.

Where radiation sickness does not lead to death, it can destroy or damage fetuses in pregnant women. Brain damage was found in many children whose mothers were less then 15 weeks pregnant in Japan when the bombs fell. Small skulls (microcephaly) occured in 44 per cent of surviving children and 16 per cent were severely mentally retarded. The fregnancy of stillbirths and post-natal infant deaths rose dramatically.

The longer term effects of radiation through delayed fallout affect those not directly affected by the explosion. In these cases, radioactive isotopes are ingested through contaminated foodstuffs and fluids, by inhalation and occasionally through the skin. Radiation-induced cancers apart from leukaemia (which occurs more quickly) can emerge after a latent period of 20-25 years. Genetic abnormalities and defects can take a number of generations before emerging since gene nutations are recessive.

Even a single bomb of the kind used on Hiroshima and Nagasaki would completely overwhelm medical resources. Quite apart from the psychological damage or the direct/indirect effects of the explosion, there would be a great deterioration in public health standard with sanitation facilities wrecked and incapable of coping with sewage clearance, providing clean drinking water and so on. Thus diseases like dysentry, infectious hepatitis an salmonellosis would be promoted. There would be diseases of overcrowding, meningococcal meningitis, diptheria and tuberculosis, diseases associated with dirt and vermin such as typhus and in Indian conditions, even plague. Common infections like pneumonia and septicaemia would become killers.

All this would be the effect of a few explosions. The effect of a nuclear war is simply unimaginable. The indirect effects would be far greater then the direct effects and impossible to calculate. As far as the environmental damage e.g to the earth's ozone layer, leading to worldwide and devastating ecological damage e.g. freezing of the temperate regions, submergence of large land masses under water, destruction of a large part of the world's agriculture, excessive ultraviolet radiation as atmospheric protection is eliminated—these are all part of what is now called the "nuclear winter" scenario which could become a reality even if there was a "limited' or "small" nuclear war in a remote part of the world.

In sum for *purely* medical reasons *alone*, nuclear war must never be allowed to occur. No government should contemplate it and it should never be allowed to happen no matter what the circumstances.

Why Nuclear Arsenals?

Why then do countries go in for building nuclear arsenals? Why then the insane nuclear arms race between the superpowers? Why then the attraction that going nuclear has for bomb lobbies in countries like India and Pakistan, which have nuclear weapons capability but have not as yet crossed the nuclear rubicon of openly deploying a nuclear weapons system?

Nuclear war is mind-boggling but precisely because it throws into the dustbin older preconceived notions of war and its possible purposes, so many governments revert back to older forms of thinking in order to cope with the mind-boggling character of nuclear weapons. That is to say, these governments or these nuclear politicians or nuclear strategic experts try to treat nuclear weapons in much the same way as they try to treat and cope with conventional weapons—they try to make nuclear weapons into *viable instruments of a country's foreign policy.* Since the uncontrollable dimension of nuclear weapons means that the use of nuclear weapons for political purposes is not viable (what possible political purpose can be justified by the use of such weapons?) what has become viable is not the use but the tnreat of its use. This is want is called deterrence. Having nuclear weapons becomes a way of assuring nuclear peace. Despite the universal character of nuclear weapons—its universal effects and the universal horror at its use—this way of assuring nuclear peace is not the least universal in character or orientation but is strongly nationalist. Deterrence becomes a way in which a nation prevents nuclear war breaking out between itself and another nation having nuclear weapons by *intimidating* it. Thus the foundation of nuclear peace is nationalist intimidation and distrust.

The great importance given to deterrence is ultimately a reflection of the bankruptly of those who have power in our societies. Nuclear weapons, as Einstein pointed out, should and must lead to a new way of thinking among human kind. Instead, very little has changed in the thinking of power elites. The best way to have nuclear peace say our tough-minded "realists" is to prepare for a nuclear war. What is more, if deterrence is to be credible, the possibility of a nuclear war at least a retaliation of nuclear attack must also be real. Thus, when governments say they do not believe that there can be any circumstances which justify the launching a nuclear weapons, they are either wilfully lying or caught in an insoluble contradiction. If nuclear deterrence for a country's government is to be meaninful and credible, its willingness to launch nuclear weapons must be real in certain circumstances.

Deterrence, then, is a justification for the proliferation of nuclear weapons. There is both horizontal proliferation (more and more countries becoming nuclear weapons powers) and vertical proliferation (the superpower arms race

and the other weapons powers adding to their nuclear arsenals). Both kinds of proliferation must be curbed. Such has been the insane logic of deterrence that both superpowers in the name of "national security" and "deterring the enemy" have embarked upon such a fast moving escalator of arms development and deployment, that both of them have enoromous "overkill" capacities. The end result of this search for nuclear security "has been ever greater insecurity vis a vis each other, and for the world". This is the historical balance sheet of all these years of nuclearly arming in order to keep the nuclear peace.

Finally, with the coming of Gorbachev in the USSR, there seems to be a chance (after three and a half decades of complete barrenness) of the possibility of the superpowers agreeing to a partial and limited disarmament in Europe. But if there is to be an escalating momentum of disarmament then public pressure and mass mobilisation on issues of disarmament must be maintained. The dangers of a new and more dangerous escalation of the arms race in space (star wars) is very much there. There is a vicious circle between the two superpowers that must be broken by external forces such as mass peace movements impinging themselves on the Kremlin and the White House. The superpowers keep on nuclearly arming themselves because they don't trust each other; they don't trust each other because they keep on nuclearly arming themselves.

For various reasons, however, the biggest danger of a nuclear war is not in Europe or the USA or Russia but in the third world where a nuclear war between the superpowers might erupt as a result of an escalating conventional war between allies of both superpowers e.g. in the Korean peninsula between north and south. Incidentally in the demilitarised zone, there are atomic mines and tactical nuclear weapons are available to the American-backed forces of South Korea.

Furthermore, rival countries with a history of mutual antagonism, such as India and Pakistan could also develop nuclear arsenals which would greatly add to the terrorism that already exist. There is already an ever growing lobby in this country demanding that India go in for the bomb now that there is growing evidence of Pakistan having a "bomb in the basement" with the "last wires unconnected". What this lobby wants other people to forget is that India exploded its bomb in Pokharan in 1974 and very likely has its own "bombs in the basement" with the "last wires unconnected". But having some bombs in the basement and openly deploying and progressively expanding one's nuclear weapons system are two different things. It is still possible to step back from the brink as far as avoiding a regional nuclear arms race is concerned. There are thus two levels at which the struggle for disarmament must continue—the global and the regional levels. One must endeavour to halt and reverse both vertical and horizontal proliferation. In the case of India and Pakistan the safest thing to do is not to get into an arms race in the first place i e to mutually abstain from going nuclear. This is what the establishment of a Nuclear Weapons Free Zone (NWFZ) in South Asia would mean. Of course, such a thing is feasible only if both countries want it, whether for the same or for different reasons. Pakistan has expressed its willingness to consider such a zone if India would, because Pakistan equates itself with India and realises that the burden of maintaining "balance" on a constantly escalating regional nuclear arms race would be much the greater fot it. Thus it is in its self-interest and not because of altruistic or "peace-loving" reasons that Pakistan is willing to jointly foreclose the nuclear option.

But India and its bomb lobby is not willing to accept such an "insulting" equation between itself and Pakistan. Thus it is opposed to such regional steps at denuclearisation preferring to argue that unless there is a halt to decline in vertical proliferation of nuclear weapons, there won't be a halt or reversal of horizontal proliferation. This is wrong. Both kinds of disarmament efforts must be pursued and expanded. Limited and partial efforts at disarmament at one level help such efforts at the other level. Both India and Pakistan should forego the nuclear option so that tensions between the two will never threaten a holocaust.

What about "nuclear blackmail" then by other weapons powers? This is a false question. There are three countries that might practice such blackmail. In the case of USSR and USA, the disparity between them and India, even if the latter had a rudimentary weapon system deployed is so great that there is no adequate nuclear riposte or counter threat to nuclear "blackmail" by the superpowers. It is not enough to have a few piddling bombs or missiles. India would have to have a much more powerful and "credible nuclear deterrent" against the superpowers, which it can never have. This is not to say that either the USA or USSR can easily nuclearly blackmail others. In fact one of the biggest problems with nuclear weapons is that their unique nature makes it almost impossible to use them effectively as political weapons. For example, how does the USA use its nuclear might to down Nicaragua and Cuba?

So the only other country from which India might have to fear "nuclear blackmail" is China, which has never been tempted to try any such uncertain process. To establish a "credible deterrent" against China, India would have to embark on a crash programme of nuclear weapons development to make up the 15/20 year technological and deployment gap between the two countries as quickly as possible. Success in such an endeavour is by no means assured. But what can be assured is that such Indian efforts would greatly perturb China and make it more willing to consider nuclear action or the threat of it against India. Such a move would also lead Pakistan to try and nuclearly "match" India and thus enhance the momentum of a regional arms race. There would be greater interaction distrust and histility and above all, greater nuclear insecurity for the countries in the region—more and more insecutiry in the name of the search for security. Nuclear security has to be a *common security* based on the virtues and strengths of disarmament not armament. It is the search for ways to disarm that hold the promise of a safer world not the search for how to use nuclear weapons in the service of national real politic. The greatest tragedy of the nuclear era is the contradiction between the regionalisation/internationalisation of effects and dangers of nuclear war and nuclear arms races and the nationalised

Health Hazards of Nuclear Cycle

manan ganguli

RADIATION is dangerous. Exactly how dangerous even experts are unsure. The more we learn about it, the more we become aware how greatly the hazard has been underestimated in the past. Karl Morgan, a founder of the health physics profession in the United States, stated, "... there is no safe level of exposure and there is no dose of radiation so low that the risk of a malignancy is zero" in *Bulletin of Atomic Scientists*, September 1978 issue. He further admitted that earlier theories of radiation effects underestimated the damage now being suffered in human populations.

Until 1934, the safe level of radiation exposures permitted to workers in radiation-related occupations was assumed by the scientists to be 52 rems per year. With the growth in understanding of the harmful effects, the level of permissible radiation dose has continually dropped. In 1934, the safe dose for the workers became 36 rem; and in 1950, a new exposure level of 15 rem per year was recommended by the International Commission on Radiological Protection (ICRP) which in 1957 reduced the exposure limit to the current level of 5 rem per year for a worker. However a double standard operates for nuclear workers and for the public—a maximum of 0.5 rem per year for any individual member of the public. And contrary to so much new research that has documented the harmful effects of current permissible exposure levels, ICRP in 1973 has recommended an increase in radiation exposure levels.

In this article, I shall explore the nature and effects of radiation especially low levels of radiation and its relation to nuclear technology.

Radiation and Radiobiology

Everything in the universe is composed of elements—the smallest particle of an element is an atom. The majority of these elements are stable, i e, they do not transform into their elements. Some atoms are unstable and emit particles and energy to transfrom into newer elements until they have changed to a stable form.

An atom consists of a central nucleus which contains almost all the mass of the atom and which is positively charged; and a surrounding cloud of planetary electrons of very little mass which are negatively charged. Normally an atom is electrically neutral and there is an exact balance between the central positive charge and the surrounding negative charge. The central atomic nucleus consists of two kinds of particles—protons and neutrons—both are very nearly of the same mass but protons have positive electrical charge whereas neutrons are electrically neutral.

Between neutrons and protons in close contact, there are very strong forces which are capable of binding them together into a stable nucleus. The stability however depends upon a rather precise ratio of neutrons to protons. If there are too many or too few neutrons the nucleus will be unstable and will remedy the situation by spontaneously changing the ratio. This can be done in the following ways.

There can be emission of a chunk of nuclear matter called particle which consists of two neutrons and two protons and in so doing the nucleus loses two positive charges. This is radiation.

Alternatively, the neutron can spontaneously change into a proton or vice-versa. In order to conserve electric charge, a P-particle is emitted which consists of an electron (if a neutron becomes a proton) or its positive analogue, a positron (if a proton becomes a neutron). This is B-radiation.

There can also be r-radiation which is a high energy electromagnetic radiation similar to x-rays. As we have seen, a substance containing unstable atoms may emit, B or r radiation by which the radioactive atoms approach stability and the process is referred to as radioactive decay. This is independent of all physical and chemical circumstances and is measured by its physical 'half-life' i e, the time in which one half of the atoms will decay. The half-life may be fraction of a second or it may be millions of years.

This spontaneous transmutation from a less-stable to a more stable state releases energy which is used in propelling the x or B-particles with considerable speed. Being electrically charged, these high speed particles interfere with the electron clouds of atoms through which they pass and change the electrical charge of the atom within a cell by disrupting its structure. This is ionisation.

We cannot sense radiation, it is invisible to the naked eye, we cannot touch, smell or taste it. But a chaotic state can be induced within a living cell when it is exposed to ionising radiation. With the sudden influx of random energy and ionisation, there may be cellular death or varying degrees of damage. This damage can be temporary or permanent.

The delicate but fantastically organised chemical substances in the biological cells can be subjected to a wide variety of types and degrees of injury. Here I shall only enumerate some major consequences. The most catastrophic result which the human body experiences in one generation is probably cancer. The cell nucleus (its store of genetic information) is damaged but the cell survives and multiplies in its perturbed form over a number of years and forms a group of cells that eventually appears as cancer. What happens between the initial radiation injury and the ultimate appearance of a cancer is still a mystery the identification of which is contemporary biology's major challenge.

Damage to Somatic Cells: Chromosomes of the cell nucleus are the targets of ionising radiation. They are considered to carry all the information to control cellular activities like growth, cell division and production of biologically important chemicals like enzymes, hormones. Ceres are the units of information within the chromosome and are composed of DNA. If the ionising radiation displaces one of the electrons in the chemical bond of DNA or RNA, there will be alteration of information-carrying chemical structure in a single gene which in turn misdirects the activities within a cell. There can be abnormal and unregulated cell-division which will produce cancer or leukaemia.

Rapidly dividing cells are more vulnerable to radiation damage. Thus an embryo or foetus suffers most while developing in the mother's womb and may be born with congenital malformation. The cell may start producing a slightly different hormone or enzyme than it was originally designed to produce which in turn may produce millions of such altered cells. This can have many adverse effects on the body such as hastening the aging process, lowering resistance to disease and precipitating psychological stress.

Damage to Germ Cells: It has even more far reaching consequences and may be transmitted to all future generations. We are probably fortunate if the damge to the sex chromosomes is such that they fail to fertilise or if fertilised the unborn baby is miscarried. But with the low level ionising radiation, we are more unfortunate. The health effects upon new generations, carried through mutated genes of human sex cells, are far more serious and pose a maddening threat.

Genetic mutations occur due to natural sources of radiation and other known and unknown causes. They form an equilibrium of beneficial and detrimental genes in the human genetic pool. Indeed, some mutations may be beneficials, but the prevailing genetic opinion indicates that any increase in the mutation rate will create a great deal of human suffering in new generations with serious physical and mental diseases. The detrimental genes if dominant are removed quickly through early death and if recessive will remain indefinitely in the genetic pool affecting generations after generations until they gradually disappear.

Geneticists and medical experts are today of the opinion that major serious human diseases like diabetes mellitus, atherosclerosis and associated heart diseases, rheumatoid arthritis, schizophrenia are genetically determined. They are known now as multigene diseases which comprise over 50 per cent of all diseases compared to earlier single-gene rare diseases like haemophilia, sickle-cell anaemia, cystic fibrosis, etc.

Sources of Radiation Pollution

There are several sources of radiation artificial and natural. In this context, the anatomy of the nuclear fuel cycle will be dealt with to understand this greatest problem of environmental pollution. Yet, other sources of radiation have to be considered with equal seriousness.

Background Radiation: Genetic disorders, diseases and deaths caused by natural radiations are no different from those caused by artifical radiation. It is estimated that 5-10 per cent of diseases due to genetic mutations are by natural radiation.

Cosmic rays from outer space and ultra-violet rays from the sun still penetrate through the present thick ozone layer of the atmosphere though it is much less than what it used to be in the past. They are gamma radiation in nature. Then, some rock strata in the earth containing uranium, radium, carbon-14, etc, release natural radiation and show high incidence of health problems in those areas. The connection between high natural radioactivity of coastal Kerala and higher incidence of Down's Syndrome in that state is well known.

Medical X-rays and Radiotherapy: This diagnostic and therapeutic procedure is one of the artificial sources of gamma-radiation. X-rays emit low level radiation, yet they are not any more considered safe. They have been several studies which have established the connection between X-rays and leukaemia, cancer and other health problems. Drs. Irwin Bross and Rosalie Bertell, analysing X-ray data of 13 million people in three states in the USA, have shown that there is significant genetic damage, large increases in leukaemia and increased susceptibility to infectious diseases as a result of relatively low doses of radiation.

Nuclear Weapons and Test Fall-Out: A 15 kiloton uranium-235 bomb was dropped in Hiroshima in August 1945 killing between 80,000-200,000 people followed by a plutonium bomb over Nagasaki with similar results. Within five years there were increases in leukaemias, cancers and mutation-induced medical disorders from radio-active fall-out. These continued to appear even 22 years after the Hiroshima-Nagasaki bombing. Without going into today's picture of nuclear weapons, it is worth noting that fall-out from test explosions by USA, USSR, France and other countries has polluted the environment with radio-active materials to such an extent that it is comparable to several Hiroshimas all round the globe.

Nuclear Industry and Radiation

The nuclear industry is the major source of artificial radiation which will be polluting our environment for many thousands of years. It is not only the reactor but the whole chain beginning from mining to fuel fabrication to reprocessing of spent fuel and waste disposal that is tremendously dangerous and there is no way of keeping the workers and the public out of radiation exposure even with the normal running of the fuel cycle. It is worth noting here that there is no safe level of radiation exposure.

Mining and Milling: The fuel cycle begins with the mining of uranium where uranium ore is extracted from the rock strata by open cast or underground method. In this process, radium-226 and radioactive gas, radon-222 which are alpha emitters are released. Radon has very short half-live (3.8 days) and is extremely radioactive and when inhaled causes lung cancer. American Indians in USA, black Africans of South Africa/Namibia, aborginal Australians, farmers in France and weaker sections in other countries have been affected most having not only been driven off their land but also having to live near these dangerously polluted mines and by working as miners.

Though the high probability of lung cancer deaths among the uranium miners was well known for a long time, no studies had been conducted until recently. Safety standards and miners' health have been neglected; compensations were denied and experts from the AEC (US) even testified that radon gas levels in the uranium mines were below a threshold level for human health damage! According to US Public Service 1978, out of 100 uranium miners being monitored from one uranium mine in New Mexico, 25 have already died of cancer while still in their forties, and a further 20 are suffering from cancer. In the report of the Australian Atomic

Energy Commission, 1975, the incidence of leukaemia/cancer among white Australian miners has been found to be six times the expected norm.

With the tragic consequences of radon gas and after many unnecessary miner deaths from lung cancer, only in 1967 were safety standards and improved ventilation of the mines introduced in US mines. Yet the uranium mining standards are not and cannot be sufficiently protective of the miner's health.

In the process of milling, i e, crushing the ore finely to extract uranium, radon gas is again released affecting the health of the workers. Milling results in vast quantities of radioactive waste products—tailings—dumped beside the mills without sufficient care. Air, surface water and the ground water are contaminated by the radon gas, radioactive particles and some highly poisonous heavy metals like mercury, lead, arsenic in the tailings. Ironically, in Colorado, they were once used as landfill or building materials for homes, schools, roads, hospitals and an airport. We have very little knowledge about the state of our uranium mine at Jadugoda, Bihar. Proper epidemiological study and health monitoring of the mining community by a team of medical experts, biologists an geneticists is of utmost importance.

Enrichment and Fuel Fabrication: For the fuel of light water reactor (like Tarapur plant), uranium ore has to be enriched to increase the content of uranium-235 by approximately 3 per cent. The process is complex, expensive and uses enormous amounts of energy. There is routine releases of radioactivity to the environment; nonetheless, solid liquid and gaseous wastes are created in huge quantity. Increases in leukaemia rates have been reported in the communities around the enrichment plants. We'll discuss the problem of nuclear waste separately.

Once uranium has been sufficiently enriched, it is sent to a fabrication plant where enriched uranium is assembled into fuel rods for reactor. During the fabrication, there is routine release of radioactivity affecting workers and to the atmosphere permitted as 'acceptable' limit.

Nuclear Reactors: A tremendous amount of heat is generated from the fission of fuel rods and this in turn generates electricity from a steam turbine as in a conventional power station. Nuclear reactors are thus a very complicated and expensive means of boiling water. Apart from the serious radiation pollution, there is thermal pollution and damage to ecological balance as two-thirds of the heat is discarded into the environment. A range of radioactive elements is produced of which only few like iodine-131, cesium-137, strontium-90, plutonium-239, are considered in the discussions.

Reactors are constructed with multiple barriers in order to keep the radioactive release as low as possible and within the containment building. Yet with the stress of heat and pressure, splits and holes occur allowing radioactivity to escape. In addition to occasional serious accidents, there is routine release of vast quantity of radioactive waste from the nuclear reactors. Of the radioactive elements produced in a nuclear reactor, plutonium is the most toxic with a long half-life of 24,000 years. Single particles weighing one-millionth of a gram, so small that they can only be seen under a microscope, can cause cancer of the lung if inhaled. Apart from causing cancer, it is concentrated by the testicles and ovaries where it will inevitably cause genetic mutations which will be passed on to future generations. Yet each operating nuclear reactor produces between 400 and 600 pounds of plutonium each year in its normal operations. Strontium-90 chemically resembles calcium and is absorbed by bones and causes bone cancer and leukaemia, Dodine-131 concentrates in the thyroid gland to cause thyroid cancer.

There have been several studies by the radiation research scientists and medical experts to evaluate the hazards of radiation at the workplace. Perhaps the most extensive study yet undertaken was that of Thomas Mancuso of the University of Pittsburg at the Hanford Atomic Works in USA. This study was independently analysed and assessed by Alice Stewart and her assistant George Nkeale, a mathematician. Stewart, a medical expert from Birmingham, had first documented the health effects of low level radiation of medical X-rays on the human foetus. Mancuso-Stewart-Nkeale study evaluated astonishing results of cancer and other radiation related hazards of Hanford workers; and US authorities terminated Mancuso's funding for follow-up study and there were even attempts to confiscate his Hanford data. Mancuso concluded that the dose required to double a person's risk of cancer *is less than half the internationally accepted limit (33.7 rad against nuclear industry's estimate of 500 rad exposure)*. Unfortunately, all these studies are yet to make an impact on the industrial and military nuclear world.

Reprocessing: In reprocessing, spent fuel rods are broken open and outer cladding is dissolved in nitric acid to separate plutonium and unspent uranium. The plutonium is separated out for use in nuclear weapons or for fuel in a breeder reactor. The process is extremely hazardous and apart from the release of highly radioactive gaseous and liquid effluents, releases routinely nitrous oxide to the air causing acid rain. There is severe occupational threat to health in reprocessing facilities and also serious environmental threat due to production of highly toxic radioactive waste.

Reprocessing has more or less been abandoned in US. Commercial reprocessing plants there have been shut down for years due to faulty technique and excessive contamination. The large reprocessing plants in operation in UK (Windscale) and France are no exception regarding radiation contamination and risk to the workers despite claims by the authorities of safe running. Besides, the Irish Sea and the surrounding environment have been heavily contaminated because of routine dumping of waste produced at these plants. The actual situation at the reprocessing plant at Tarapur is not known; it is said that the planf is inoperative due to contamination.

Waste: As we have seen, nuclear fuel cycle generates vast quantities of radioactive waste at all stages. They have been divided into three categories—high, intermediate and low level, by the concerned international and national authorities. Low level wastes are considered as a low hazard potential. Referring to earlier discussion, it appears that a 50 per cent increase in genetic disorder and diseases are considered by

Don't Just Reduce Risk—Transform It!

dave rosenfeld

In order to ensure a specially high degree of safety, the job was so highly compartmentalised that those in different departments often could not or were not allowed to communicate with each other.

—Robert Jungk, on the Cap de la Hague reprocessing plant, in The Nuclear State

It would be possible to write a history of the inventions made since 1830 for the sole purpose of supplying capital with the weapons against the revolt of the working class.
— Karl Marx, Capital, *Vol 1.*

THE arguments for nuclear safety have become familiar: 'The risk from a radiation does of 1 rem is the same as the risk of being obliged to smoke 1/20th of a cigarette every Sunday', claims Walter Marshall, chief of the Central Electricity Generating Board (*Atom* October 1982). Independent studies conclude that nuclear electricity in the whole fuel cycle gives fewer deaths per unit of electricity than does coal (see Table in Appendix). The argument appears absurdly simple, yet anti-nuclear objectors get locked into a debate on the exact level of risk from reactors, reprocessing plant, transport bottles, dumped nuclear cargoes and nuclear disposal sites. Hiring experts to challenge the well-funded orthodoxy is expensive. Counter-experts are marginalised from the 'scientific community' and are denied even minor funding. Some, like Professor Sternglass, have been crudely attacked as 'fearmongers'. Some scientists find themselves moderating the objectors' 'overreaction' as they see the risk as numerically low, even if it is really at double or treble the industry's risk figures. For the anti-nuclear side the debate is demoralising and endless.

But there is more at stake than simply challenging the true numbers of deaths due to each technology. The very idea of quantitative 'risk' contains hidden assumptions that influence not only the style and outcome of the debate, but also the detailed choice of technology by industry's managers. This article will draw out some hidden assumptions and challenge them. I end by showing that this is not merely word-play, as the analysis gives useful perspectives for a number of radical science issues, not least nuclear safety.

What is This 'Risk'?

Risk determination is used by the nuclear industry in all its safety cases to marshall safety information, from a number of disciplines, into figures of expected deaths, accidents or disease per reactor, per disposal site, per unit of electricity, etc. For the initial breakdown of equipment, elaborate engineering models ('fault trees' and 'event trees') are used in what's called 'probabilistic risk analysis'. For the spread of contamination, environmental modelling is used. For the effects of radiation on the exposed workers and residents, toxicological models (of 'dose-response') are used. It is not claimed that the models yield causal predictions. Rather they give a figure of risk that is said to give the chance of harm from nuclear power, or from coal when applied to coal. The calculation of risk figures use disciplined methods and are arguably worked through with a degree of scientific rigor often lacking in safety analyses. Yet the actual notion of risk, defined as 'probability of harm', has so far gone unchallenged. And it is precisely this notion, when it is analysed, that turns out to be the vehicle of prevailing prejudices about technology.

Hidden meanings can be seen once we ask why 'risks'—seen from presentations of tables of deaths, in say coal, nuclear or other industries—always seem so fixed. These figures, we are told, represent the risk of an industry, or rather, it is implied—and this is the crucial unspoken step—the hazards *due to the technology* alone. Thus the 'risk' of nuclear power is 1 death in a million people per year. When risk analysts look at average accident rates over decade periods and claim that, on current improvements since 1940 in the coal industry, mining deaths will be down to 0.3 per 10,000 per year by 2000, it reinforces the inevitability and asocial character of risk. It is simply the 'risk of a technology'. We can only wait for the technology to become safer.

This kind of fatalism is reinforced by a risk analysis that excludes the social relations of hazards and so makes risk into a thing, as an inherent, technical property of a particular technology. This definition of the problem serves to relegate 'decision-making' to elites acting on behalf of potential victims. In particular it uses 'risk reduction' to justify supplanting older skilled technologies with supposedly 'safer' ones (coal vs nuclear), or adding on extra 'safety devices to dubious designs for nuclear technologies (British-style PWR for Sizewell).

The prevalence of risk analysis (or 'risk determination' as they call it these days) in the Great Nuclear Debate raises some important issues for the politics of science. Its use is based on the idea that risk is due to a technology and measurable as probable deaths per year. This idea rests on several definite assumptions, rarely spelled out: 'risks' are *in* technology, asocial, randomly striking and quantifiable. Once having analysed these assumptions we will see the dangers of being led to tilt at technology, and of acutally inviting greater managerial control of work via the choice of the 'least risky' technology.

The assumptions that lie behind risk as the 'probability of harm' are as follows:

(1) *The calculated risk is due to the technology alone* (in the sense of 'hardware'). Thus the risk figure is applicable with the same technology to Britain and Brazil, to 1983 and 2003, to managers and workers.

(2) *We are 'exposed" to risks that strike from within the technology; the probability of harm is the probability of being hit.*

(3) *The risk is randomly striking.* For the use of probability:

a) The specific hazardous encounter with technology is identical every time.

b) The risk *exists* in every encounter, but it only *strikes* with harm as the 'outcome' in a few cases, entirely at random.

c) This randomness gives rise to the fluctuations around an average number of people struck per year, as a hand might draw differing numbers of peas from a black bag, but always approximately a handful. It is the average number of deaths that is measured by probability.

(4) *The quantifying of risks makes all activities comparable.* The essential part of this 'risk' is its numerical level. Once that is known, the essence of the risk is grasped. Otherwise incomparable activities can then be compared by ranking them on a scale.

The current use of risk analysis, then, leads us to a particular view of the structure of hazards—risks are asocial, they are external, they strike randomly. If the construct of the risk analysts is to be believed then we are surrounded by randomly-hitting techno death-threats. Is it some kind of macabre prediction when we are given the retort, 'Well, *everything* has a risk?, Is it a wonder that analysts speak of people as being risk-averse?

Safety Science Is Dangerous

How valid is this description of hazards given by risk-analysis? We shall look at its assumption. Some are easily debunked, while others are more subtle.

(1) *Is risk due to technology alone?* For workers from a workforce to die year in, year out, in similar numbers, they must be born, fed, clothed, transported to work, trained, ordered, paid, put in hazardous situations, kept healthy or replaced. In short such statistics require that the whole system that gives rise to the hazard is reproduced. Mortality and morbidity figures for industries, then, do not simply measure some 'technological risk'. Rather, they measure the overall *social reproduction of industrial harm*. That is, they measure social and economic forces that bring people into contact with hazards as much as they indicate any intrinsic hazard of working with the hardware. Accepting the false assumption leads to a false strategy. Attacking technology as the cause of the intolerable hazard will only solve half the problem—you must attack the forces bringing the technology into being, or else a substitute for the same purpose will be found.

(2) *Is risk a thing that 'exposes' and strikes us from within technology? Do risks always strike at random?* These questions are linked by the idea of an alien threat hitting in an unknowable way from outside our experience. Are hazards in essence randomly striking alienated threats? The answer is not straightforward: yes or no. At one level, some hazards do strike randomly. For example pipe breaks in complex plants carrying toxic materials are due to metal fatigue or mechanical failure that is basically a random process. Likewise the effects of exposure to agents like radiation, viruses, invisible asbestos fibres occur in individuals in a way which is governed by random biophysical events.

However, the assumption is false at another level—that is, at the level of individual or collective control over a hazard. Take the case of detailed control by operators over a task. To speak of the 'exposure' to the risk of cutting your own finger with a chisel (assuming the blade is perfect) would sound odd to the skilled craft worker. The ordinary risk of a cut finger is not random to the woodworker since it arises at well-defined times when care can be taken to avoid it. It is the term 'skilled' that we associate with remedial actions being on a human scale, where the 'exposed/at risk' categories would misrepresent that control.

In the case of collective control, information on workplace organisation can transform the nature of risk. For example, ask a worker at the Windscale nuclear fuel reprocessing plant to repair pipework in a high-radiation area unfamiliar to him. Even if there are only a couple of lethal 'hotspots' where doses are high, the whole area appears hazardous. To him (women are not employed in high-radiation zones) a walk in a straight line is like crossing the road blindfold. As the management gives him a chart of hotspots and a pocket alarm meter, he feels sure to avoid deadly spots, confidently and consistently—as long as experience tells him that the management or union safety committe have assured the chart meter are reliable.

In this example, if two areas had the same death rate, it would be preferable to work in an area A (most of which had lethal hotspots but where you're given accurate, trusted information) than in an area B (with very few lethal areas but no clue where they are). If some workers have died in areas A from carelessness, it seems less of a problem to negotiate than if the same number died in area B from a withering beam by bad luck. *The randomness of the risk depends on workplace relations.* So at one level there are indeed randomly striking hazards e g, cancer risks from radiation, viruses, chemicals. At another level hazards are subject to detailed control, so that harm is due to bad design, bad procedures, poor training, poor information or carelessness, e g, woodcrafting and work in 'hot' radiation areas.

(4) Quantification adds no further assumption that is not already made in the earlier points. However, the acceptance of such numbers as inherently comparable serves to hide the assumptions that we've identified.

By assuming that all hazards are randomly probabilistic, risk analysis treats people as passive objects of technological hazards: individual and collective consciousness are ignored. The immediate consequence is that, in general, *strategies to reduce 'risk' evade the issue of control over safety instead encouraging a 'lower risk' technology that is alienated from worker and community control.* The problem is not too little management attention to safety analysis, but too much. The quantitative comparison of different risks encourages deference to the intrinsic 'risk of a technology' and thus to management control over safety.

Historical Origins of 'Acceptable Risks'

How does 'safety' get reduced to a technical choice among different technologies or different devices within a technology? This is done so compellingly by risk analysis by quantifying risk as the probability of harm, yet while hiding the assumptions involved. The 'nuclear is safer than coal' argument, then, involves more problems that the simple, hopeful predictions about nuclear accidents and health damage from radioactivity. More insidious than that, the whole framework treats the harm from each industry as

technical, fixed, while at the same time pretending not to make value-judgements. Ironically, this type of risk-analysis arose from an historic admission of 'no safe level'. Let us see how.

1966 was a turning point for risk analysis. The International Commission on Radiological Protection (a self-appointing, non-governmental body) accepted that radiation may have no safe level of exposure for cancers and genetic defects. Secondly, in that same year a fast-breeder reactor near Detroit burst a fuel pin and partially melted down, thereby exceeding its official 'Maximum Credible Accident'. The safety engineers quickly realised that automatic safety devices can and do fail, so that there is no accident that could be made strictly impossible by engineering safety features. So by 1967, both in toxicology and in engineering, it could no longer be assumed that risks had a 'safe level' that could be found scientifically.

Since the acknowledgement that some hazards have no safety level, new theories of how to predict risks from drugs, rays, bugs, chemicals machines and industries have arisen together with social theories of how to resolve conflicts over safety. One model, popularised by W W Lowrence in 1976, particularly captured the minds of researchers. It appeals to the administrator role of professionals in the scientific/industrial/managerial world. In this view:

i) Everything has a risk—most agents, technologies, occupations, leisure. The magnitude of this is a technical judgement for scientists.

ii) Scientists should rightly avoid statements that something is 'acceptably safe', which amounts to a political judgement.

The view is articulated as follows. No longer can scientists simply show that risks are non-existent and then reassure the union, the patient, the plaintiff or the tenants association. As risks always exist on a numerical scale, a safety standard represents some level of hazard. So someone (society, not the scientist) must either ban the technology or set an acceptable level of hazard, given the benefits of the technology. In effect scientists purport to present simply the facts and then allow others to set 'acceptable risks' within that rigged framework.

Faced with a new technology, or a newly contested one, scientists must now find the objective level of risk from a whole range of exposures. A new science, *risk analysis*, was painstakingly developed, supposedly to give a predicted sliding scale of risks from different levels of technology. This scale was to be input to *decision-making*, where conflicts are resolved by choosing to expose people to a level of risk which is outweighed by the benefits from the risky technology. The decision-making could operate 'rationally'—that is, by using economic arithmetic to spend the limited safety and health resources in proportion to the level of risk.

However, decision-making will be bedevilled by the need to make expedient decisions because, so the model goes, the level of risk people tolerate and the vigor of opponents to risky projects is not in proportion the 'objective risk', as ascertained by risk analysis. People (not the numbers) must be wrong, ignorant, vindictive or irrational. Decision-makers therefore need a second input, apart from risk analysis, namely a socio-psychological study of why people's reactions do not correspond to the objective level of risk.

This whole view, originating in the nuclear and aerospace industries, was seen as the proper way for scientists to set about denying adjudicating on 'acceptable risk'. And, so it appears, scientists could voluntarily abdicate the politically-laden role of reassuring on safety (if only they would!) and could instead retire to the rigorous and objective world of toxicology and safety engineering methods in the new science of risk-analysis. Appealing though this scheme is, however, it has been openly admitted that risk analysis is not entirely objective. And this admission has jeopardised the credibility of 'rational' decision-making and socio-psychological studies of people's irrationality toward risk.

For example, in developing measures of the risk of an industry, risk analysis has used various ways of combining the incidence of different accidents and diseases into an index that would measure the total amount of harm. However the conclusion became inescapable that, where these grand indices were used, risk analysis was making moral judgements. For example, if we simply add days of work lost from different diseases per year, we make judgement about the relative amount of harm from physical versus mental suffering, suffering long versus dying early, frequent isolated deaths versus infrequent mass-killings.

To avoid making such obviously moral judgements, practitioners decided not to aggregate diferent forms of harm. The disciplines of safety engineering and toxicology can systematically analyse failure rates of machines and arrive at does-response curves for toxins. Mathematical formulae then come out with probability of harm per year for *each type* of injury or disease separately. It is these well-defined methods, usable by anyone, together with the experimental data and industrial accident data, that supposedly make risk analysis figures objective. It is only by a detailed look at the definitions of risk (as in the previous section) that we were able to get to grips with this last formulation and understand precisely how risk analysis is value-laden.

Practical Consequences

Risk analysis lies at the heart of the prevailing idea of acceptably risky technologies. Debunking it (i) is useful in general radical science perspectives, (ii) informs some perplexing questions for anti-nuclear campaigns, (iii) opens up an approach for opposing safety analyses that use probability and (iv) facilitates intervention in the 'risk debate'.

Firstly, we have worked through an example of how science clearly acts as ideology. The scientific content—here the very definition of 'risk'—is the vehicle of the manager's right to dominate workers' activities. New questions arise: Should socialists abandon entirely the elaborate and rigorous methods of engineering risk analysis? Is there a socialist science of risk? Will the simple expedient of stating the social relations of (quantified) risk overcome the objection?

Secondly, we can see how the dominant managerial definition of nuclear safety fits well into the wider nuclear project. Although nuclear energy will not deliver any net *energy* until after the turn of the century—due to a net consumption during the construction part of the programme—it could

generate 30% of *electricity* by 2000. That is much more than nothing at times when transport workers or miners block the remainder.

> ...a nuclear programme would have the advantage of removing a substantial proportion of electricity production from the dangers of disruption by industrial action by coal miners or transport workers. —leaked minutes of Thatcher's Cabinet Sub-Committee on Economic Strategy, October 23, 1979 (originally published in *Time Out*)

Nuclear safety systems

—require often intense workplace discipline, e g, the restrictions on internal communication at Cap de la Hague;

—require no-strike agreements to achieve their assumed performance; and

—rely on highly qualified scientists whose work and attitudes are highly integrated into management perspectives.

Risk analysis, portraying risk as a neutral quantitative matter, paves the way for work organised under nuclear managers' discipline, even blackmail, all in the name of *more* safety. Is it not preferable to back coal, where a knowledge and control of the system by workers give higher chances of winning a better safety deal than with the polutonium state? What guarantee is there that current nuclear safety standards will not be eroded when the Tory government has further cowed workers and other opponents with nukes? Already Reagan has been declaring the nuclear industry to be 'over-regulated', and promising side-steps to licencing hearings.

As scientists are involved in designing and assessing technologies, they should be aware that their work influences the relations of control. When people reject 'dread hazards', this is not simply a matter of their ignorance of 'the true risks', but a sign also that no trust has been built between people facing hazards and those in control. Sometimes distrust comes from consistently negative experiences, as many shop stewards in industry will testify. But in other cases it is a sign that there is no consistent experience that people can rely on. In short, there is a gulf between people's experience of technological change and scientists mostly aligned to managerial priorities, as defined especially by risk analysis. It is this class nature of scientists role, and not some fundamental irrationality of people, that generates hostility to new hazards.

Thirdly, is it possible to challenge nuclear science as science? The technical literature clearly paints the picture of a systematic safety programme that's the envy of chemical safety campaigns. Time and again the literature asks whether this effort is 'enough'. It seems a logical definition of the problem. Yet once we are in the thick of the numbers game, it is hard to challenge the expensive and extensive studies that show nuclear power as 'relatively safe' or 'about as safe as coal'. Most critics stick to the general issues of the politics of plutonium, rather than wade through the swamp of reactor science, radioecology and radiotoxicology. There has been no analysis that criticises nuclear science as a starting point for identifying the problem. Our analysis removes this quandary. By analysing the precise use of probabilistic risk, we can argue specifically on the science of safety and win! That is, we can expose the class base of the technology by dissecting a key scientific concept, quantitative 'risk'.

Lastly, radical research on safety is given a new focus by this analysis. We've discovered that the key debate is not

Low-Level Radiation – Out of Control

Workers at Windscale experience, by and large, a comprehensive programme for avoiding the 'hot-spots'. This programme has engendered a basic confidence that risks are under control. At the plant, workers are understandably quite defensive when 'outsiders' allege that their work is dangerous, as they find themselves identifying with management on the safety issue.

This attitude affects relations over the low-level exposures. With low-level radiation, in contrast to the high-level situation, there is no alternative to an intrinsically random. untouchable, unknowable hazard. You do not even know whether you have been affected until twenty or so years after the event. Routine, random low-level exposure is tolerated in the knowledge that the chance of harm per person is very remote.

But this 'knowledge' is chimerical and entirely different from daily witnessing a competent hot-spot management operation. For low-level work, badges are issued and exposures tallied, but the knowledge of the hazard is available only from scientific studies. BNFL's interpretation of the studies is accepted. This acceptance might be seen as a spin-off from the confidence won from their track record in hot areas, their vindication by 'independent' Government bodies and their success in dealing with scientific challenges in the press and at inquiries. As BNFL win this confidence game, the scale of low-level radiation risk remains uncontested as a workplace issue. (What has been contentious is the administrative practice of 'burning out', or exposing unruly workers to the yearly maximum allowed radiation, thus disqualifying them from further work in the year—but this is not directly linked to the 'randomness' issue.)

This historical aquiescence by most workers, on the lower-level exposures, should not distract from the very different relations of control. With high-level exposures, concern is highlighted when for example a direct injury occurs, with visible effects within hours or days. The response is obvious: press for effective measures to prevnt any repetition, with whatever muscle you have. With low-level exposures, your concern over getting a cancer or deformed kids is heightened only by claims that the old risk-estimates are wrong, that it's more dangerous now. Workers don't control science; the pronouncement could appear to come out of the blue unless you have reliable information from scientific allies. And you have already been exposed; you cannot change that fact. Without those scientific allies with a proven track record, the choice is between management's reassurance and abject worry. Thus the class role of scientists is crucial.

about the level of risk from Sizewell B's proposed PWR. The numbers used in risk analysis talk only about the hardware failing. When operators are mentioned, the chance of 'operator error' is used entirely as if operators were hardware, albeit defective. At nuclear plants we must expect that the real failure rates will be dependent on the social system that organises it:

Real responses of thinking, waged operators
—Workers may be on strike in a minor accident sequence.
—Management commitment to a training programme may lapse.
—Complex but infrequent modes of failure may happen in too short a time for anyone to cope.
Smoothly running quality assurance programme
—Subcontractors may falsify quality inspections (and have done so).
Smoothly running maintenance programmes
—Non-unionised temporary maintenance workers may rebel against 'burning out' practices.
Effective inspection programmes
—Inspectors close to the industry may be lax, believing risks low. (Hendrie, chief US regulator, was sacked after Harrisburg.)
'The techbology'
—Like each car, each reactor has its own unique history of construction and maintenance.
—When politicians like Reagan (or an 'over-regulated' industry) change standards, the PWRs built and maintained may be different.

In non-nuclear safety there is an increasing tendency to follow the assessment methods developed in the nuclear energy debate. In fire safety, asbestos control and chemical plant safety we see use of 'cost benefit analysis', 'reasonably practicable reductions', 'engineering risk assessments'. These all rest on the idea of balancing costs of reducing 'the risk' against supposed benefit of using the technology.

There are many obvious questions to raise about these schemes: Who benefits from the product? How do you measure the cost of life? Our approach goes further by challenging the scientific definition of 'the risks' that were measured in the first place and that were assumed to exist in the technology as a thing, not as an organising system. Through our approach, the question of control over the risk can be made central to the debate even before monetary costs are raised. Indeed, the particular social construction of nuclear risks turns out to be less a cost than itself a benefit to nuclear management.

The numbers game has often led environmentalists and hazards campaigners into a blind alley of demanding 'zero risk'—an idealistic and unrealistic focus. This quandary points to the real difficulties with either rejecting or accepting a (supposedly apolitical) 'balance' between health 'costs' versus industrial 'benefits'. That kind of choice usually confronts us as utterly compelling, universal rational. For example, could socialist societies delay reconstruction programmes until all industry is conclusively proven 'safe'? Our approach offers a way out of the quandary: while defending the primacy of health, we can assert the issue of control as central to any 'acceptability' of hazards in the name of wider benefits.

In conclusion: Beware the 'low-risk' technology of safety science, which serves to usurp control over hazards and thus guarantee management's safety from workers. The important safety question facing workers and communities is not some precise, numerical level of safety. Rather it is how we can gain detailed control over deciding which risks we take, so that we are confident, at all times, they're worth the benefit. How do we transform alien hazards?

the international atomic energy authorities as a small hazard.

Safe management of radioactive waste is an unanswerable problem of the age because toxic products are not only highly lethal but remain radioactive for several million years. The more we go nuclear, the more we are adding to the problem of survival of our future generations.

There have been some romantic suggestions disposing of toxic waste from the earth by rocket into space or deep burial under the Antaractic ice but no adequate solution has yet been devised. Uptil now only high level radioactive wastes are stored in carbon or steel-concrete tanks which last 30-50 years; and low and intermediate level wastes are either dumped into the sea or buried underground in concrete silos. Proposals bave been made to solidify the highly toxic waste in glass blocks to be stored in shafts drilled in the seabed or under hard rock.

All the attempts and plans are far from reaching any real solution. There have been leaks from the storage sites contaminating the surface and ground water and the atmosphere and causing serious health hazards. We know very little about India's waste management programme.

The operation of a nuclear reactor generates astronomical quantities of radioactive waste of different types and of varying half-lifes ranging from a few seconds to a few thousand years. The amount of radioactivity produced from these elements is in direct proportion to the operation of the reactors. Even after Chernobyl which has put a big question mark on the future of nuclear power, India's nuclear policy is unchanged. We have an optimistic plan of 10,000 MW electricity from nuclear plants by 2000 AD! It is estimated that one year's operation of a 1000 MW nuclear plant generates fission products equal to that of a 23 megaton fission bomb; that is more than 1,000 bombs of the Hiroshima size.

Safe, permanent and absolute isolation of these radioactive poisons from the environment is the only condition for nuclear power to be acceptable. And this is simply not realistic. There is no disagreement today about how much radioactive poison is produced by the nuclear power plants. There is little or no disagreement about how lethal these poisons are. The disagreement lies in the quality and quantity of routine release of radioactive elements during all steps of the nuclear fuel cycle. Will the nuclear advocates give a satisfactory answer to this? No, they cannot and will not. The only answer is:

STOP NUCLEAR POWER

The Numbers Game

Occupational Health Hazards at Indian Rare Earths Plant

v t padmanabhan

The Department of Atomic Energy is currently pushing forward its ambitious plan involving a ten-fold expansion of nuclear power generation by the year 2000. This would involve the setting up of a number of nuclear establishments and would expose a number of people, workers and neighbouring communities to varying degrees of excess radiation. The Indian Rare Earths is the only DAE venture which has completed 30 years of operation, which incidentally is the average latency for cancer which is just one of the health hazards of exposure to radiation.

This paper (condensed from the Economic and Political Weekly, *March 8-15, 1986) reports a retrospective epidemiological study of workers at the Rare Earths Division of the Indian Rare Earths Limited, Alwaye in Kerala. The study examines the mortality profiles of workers for the last 15 years. Workers at the nearby Travancore Cochin Chemicals and those insured with the Employees State Insurance Corporation are taken as the control populations. The study demonstrates a significant difference in the incidence of cancer and mortality due to heart diseases and all causes between the IRE workers and the control populations. The incidence of sterility among the IRE workers and genetic disorders among their children also appear to be high. However, a study of this sort can only formulate a clinical hypothesis. There is an urgent need to institute a comprehensive, inter-disciplinary study of the plant and the workers. Such a study cannot unfortunately be conducted by independent workers or research centres because the Atomic Energy Act of 1962 prohibits any such inquiry into the affairs, including health and safety issues, of the DAE.*

AN Occupational Health (OH) study involves the use of multidisciplinary techniques of medicine, environmental science, social science and law. To be complete, the study should focus on the health status of workers, quantify the pollution load in the work environment and study the health and safety apparatus available including the internal safety organisation and compensation structure, etc.

In this paper, an attempt is made to study the health status of workers of Rare Earths (RE) Division of the Indian Rare Earths Limited (IRE) Udyogamandal, Ernakulam, Kerala. IRE, an undertaking of the Department of Atomic Energy (DAE), is engaged in the processing of monazite sand found in abundance in Kerala and Tamil Nadu coasts. The plant under study has a processing capacity of 4,000 tons of monazite a year. The main products of IRE are thorium, rare earths (RE) chloride and zirconium. Thorium is at present used in the production of gas mantles. The metal, which derives its name from Thor—the Scandinavian war god—would be used as fuel in breeder reactor which is still in research stage. Zirconium is used for cladding of uranium fuel pellets for atomic reactors. The other important product—RE chloride—is used in the chinaware industry. India commands a share of one third of the world market for this product.

The Health and Safety Division (HPD) of the Bhabha Atomic Research Centre (BARC) under DAE is entrusted with the sole responsibility of health and safety of workers in units under DAE. The Atomic Energy (AE) Act, 1962 prohibits an independent scholar or a research centre from making any inquiry into the affairs of the DAE, including the health status of its workers.[1] Even though the DAE units employ more than 20,000 people, no data regarding workers' health status is available, except, of course, occasional briefings to the press made by the official spokespersons.[2]

In this section, the production process at the plant under study is described briefly and an attempt is made to identify some of the more hazardous locations found on visits to the plant.

The main raw material used is monazite which is an orthosphate of 15 rare earth elements and thorium. The sand is ground in the ball mill to 400 mesh size after which a suction pump pulls out fine dust through a filter and deposits it in a bin. Dust is then mixed with dilute caustic soda (lye). The solution is then pumped into the attack tank where caustic soda (flakes) is added. The solution is then moved to arelay tank and leached with water. The first product of the process—Trisodium Phosphate (TSP)—a general purpose detergent—is decanted here.

The remaining slurry containng hydroxides of rare earths, thorium, uranium, mesothorium and lead is pumped into a set of 'More Filters' where it undergoes filtration and washing. Traces of phosphate are removed and slurry is pumped into four extraction tanks where concentrated hydrochloric acid is added. At this stage, the RE fraction of the compound becomes RE chloride which is drained out and pumped into a deactivation tank in which barium chloride and sodium sulphate are added. Deactivation involves separation of radioactive elements like uranium, thorium and their 'daughters'. These as well as lead are then allowed to precipitate in the tank. The precipitate is mechanically separated through press filters. The clear solution which is pure RE chloride, is decanted and the precipitate is scrapped off the press filters manually. Thorium hydroxide is also sent to another set of press filters to remove traces of RE chloride. Thorium hydroxide is scraped manually and pumped into a silo.

While no spot in the IRE compound seems to be free of radioactivity, there are a few processes which involves considerable threats to the workers. Let us consider a few examples:

(a) *Ball Mill*: The mill where monazite is ground is not air tight. There are numerous holes through which dust can escape. Moreover, mill vents have to be opened frequently for sample collection. This is done manually by the operator/helper. Though respirators are given, the workers do not wear them because: (i) it is uncomfortable; (ii) since a worker has to attend three spots, it is inconvenient; and (iii) since the volume of air breathed is reduced considerably, the worker is not able to cope with the work-load.

(b) *Filter Press ('Cancer Ward')*: At filters where thorium and

mesothorium are pressed into cakes, materials handled are richest in radioactivity. Here work is done in pairs, each worker standing on either side of a 10′×2′ rectangular press, with a series of wooden frames. The top of the press is at chest level. The sticky concentrate has to be scraped from the frames using a metal sheet as big as a kitchen knife.

Workers on this job are given gum boots and rubber gloves. On the day of our visit, one of the two workers was not wearing gloves. He said that with gloves, the speed of work is reduced considerably. The plant superintendent who accompanied us did not ask him to use the 'protection gear' either. Mesothorium has gamma activity. Rubber, in any case is not a shield against this.

(c) *Lead sulphide disposal*: Lead sulphide (which contains lead, mesothorium, etc,) collected in the RCC barrels remains unsealed for a week. The barrel is located by the side of a road leading to the canteen/dispensary. They are sealed once in a week. After a year or so the barrels are buried in the factory compound itself by a disposal team consisting of a crane operator from the Fertilisers and Chemicals Travancore Ltd (FACT) and contract workers. The latter have to remain close to the barrel for securing its hooks.

According to the International Labour Organisation (ILO) guidelines, this class of radioactie waste can only be handled in "sealed-in operations, with people working in plastic suit with controlled ventilation".[3] In IRE, workers wear only cotton khakhi uniforms.

(d) *Thorium Silo*: Wet thorium hydroxide, kept in silos is removed occasionally for transportation to the Trombay facility. (This is a Government of India-owned company which is under the management of the IRE. Here, thorium hydroxide is converted into thorium nitrate for gas mantles and thorium oxide for research purposes.) Since silos contain many hundred tons of thorium stored for over three decades, there is the possibility of a high concentration of thoron, a thorium 'daughter' in gaseous form. According to ILO, air in the silo has to be evacuated once in every 17 minutes.[4] There is no facility for this in IRE. With radionuclides and thoron gas, work in the silo can be equated to both a radiation bath as well as a radiation dust bath.

(e) *Open Vessels*: Almost all chemical treatment is carried out in open vessels. Spillover of considerable vintage has accumulated all over the vessels. Because of the openness, radionuclides and thoron gas float freely in the workplace. In almost all processes, the external skin contamination is totally unavoidable because of the bad housekeeping. According to the plant superintendent the vessels as well as the floor, which appeared no different from a paddy field during transplantation had not been cleaned for over a decade. While the above hazards are of a day-to-day nature, there are riskier operations which have to be performed periodically. Some examples are given below:

(a) *Digging the Pond*: After extraction of TSP, the remaining slurry is washed in three tanks. The slurry is moved from tank to tank with an electrically-operated crane with a maximum capacity of five tons. At times, when the slurry is beyond the carrying capacity of the crane, or due to some other faults, it has to be removed manually. Workers, usually new recruits, enter the tank with a shovel. They can wear their gum boots and rubber gloves, if they wish to. The slurry is removed with the shovel and this job is known as 'kulam vettal" which, in Malayalam, means digging the pond. The approximate frequency of this event is one a month. The tank contains hydroxides of rare earths, thorium, mesothorium and uranium which have alpha, beta and gamma activity.

(b) *Digging the Grave*: Lead sulphide, the main solid waste, which contains mesothorium and other radioactive materials, is stored inside an RCC barrel which can accommodate 200 kg, the approximate output is more than normal, excess quantity bulges out of the polythene bag kept inside the barrel and is removed manually with a shovel. This has to be done approximately once every month. The materials have beta and gamma activity.

(c) *Occasional Activities*: Apart from these, occasional activities like shifting of godowns are done by contract workers. During 1983, dock workers of Cochin were employed to remove thorium concentrate stored in IRE godown near the port. According to an eyewitness, many of the MS drums in which the concentrate was stored were corroded and broken. During January/February 1985, casual workers were employed to shift thorium produced during he early fifties to the present silo. No protection was given in the above cases.

Among the permanent employees, the exposure rate is not uniform for all categories of workers. While helpers remain in close proximity of the production process, operators and supervisors who do not have to do much of a manual handling, remain a little away from it. However, the management has made it a point to evenly distribute hazards among all the workers. This has been achieved in two ways: (i) In IRE, there is only one entry point for workers, they are recruited as helpers. The posts of operators and supervisors are time-scale-promotion based; (ii) After a complete monitoring of the plant by HPD in 1966, permanent posting of workers to separate sections within the production line was discontinued. A rotation system was introduced under which every worker moves out of one section after a fixed interval.

The production technology was imported from France where it was developed in the forties and is outdated by nearly half a century. During those days, the awareness of radiation hazards was at a very low ebb, restricted as it was to a few radiologists. Between then and now, developments of a far-reaching nature have taken place. In IRE, however, the increased awareness of radiation hazards has not lead to any innovation to prevent it at source. Instead, cheap and totally inefficient measures like gloves and gum boots have been resorted to.

The Numbers Game

In a latter addressed to the Prime Minister April 15, 1985 Professor K V Thomas, member of the Lok Sabha from Ernakulam, alleged that 14 workers of IRE died of cancer between 1970 and 1984. The prime minister in his reply (April 23, 1985) promised that he would have the issue examined. Earlier, in a memorandum addressed to prime minister, all the recognised trade unions of IRE had pointed out that the high incidence of cancer among workers can be attributed to radioactivity.

In our review of literature, we saw that the cause-effect relationship between radiation and diseases like cancer, genetic disorders, etc, has been well established. However, these diseases can also be caused by agents other than radiation. There is no

way to ascertain the initiating factor in carcinogenesis at present.

Since occupational diseases do not carry a label indicating their origin, indirect methods have to be resorted to understand their aetology. Causative relationship between an agent and a disease is established through epidemiological studies, in which the incidence of disease in the exposed population is compared with that of a non-exposed population. An epidemiological study can be either retrospective or prospective. In the former, disease/deaths which have already occurred in the past are studied. In contrast, a prospective study is futuristic, the student waits for the event to occur. If a clearly identifiable trend is discernible, it is ethically sound to study the past, so that speedy remedial action can be initiated.

In this section, the incidence of cancer and mortality due to heart disease and all causes during 1970-1984 among IRE workers is examined. In an epidemiological study, the two population compared (the exposed and the control groups) should belong to similar socio-economic, age-sex groups.

Given the weakness of available estimates/data, use of a sample of industrial workers sharing a common socio-economic background would yield mroe reliable results. Adjacent to IRE, there are three more industries which form a cluster. There are the Hindustan Insecticides Limited (HIL), producing organochlorine pesticides like DDT and BHC, the Fertilisers and Chemicals Travancore Limited (FACT), manufacturing nitrogenous and phosphatic fertilisers and the Travancore Cochin Chemicals Limited (TCC) producing caustic soda, chlorine, etc. HIL and FACT have carcinogens in the work-places, like BHC and DDT in the former and rock phosphate which contains uranium in the latter.[5] None of the chemicals handled in TCC is known to be cancer causing. Moreover, since both IRE and TCC went on stream during the same year, the age composition of workers is more or less similar.

In TCC, caustic soda is produced by electrolysing sodium chloride (common slat) using mercury as cathode. Mercury is highly toxic; chronic exposure can cause neurological and skeletal disorders. Workers are also exposed to heavy concentration of chlorine which is a by-product. Over and above the pollutants released by their respective industries, the workers of both IRE and TCC have to live with invading pollutants from neighbouring factories—sulphur dioxide, ammonia and fertiliser dust from FACT and DDT from HIL.

In terms of wages and perks, both the population groups are on a more or less equal footing—the only difference being a higher rate of bonus and a liberal housing loan in IRE. On the health care front, workers receiving less than Rs 1,000 a month are insured under ESIC. Those earning above Rs 1,000 have a company medical scheme under which expenses incurred on treatment of workers and their families in private hospitals recognised by the management are reimbursed.

TCC has a residential colony in Udyogamandal itself, which is high pollution zone.[6] In contrast, workers of IRE have their residence scattered in the entire district. Hence, the pollution load in the living environment (beyond the factory) of TCC workers is higher than that of IRE.

In this study, we have used the workers of TCC as well as those insured under the ESIC as our control populations.

In the case of cancer, there is a time lag between the crucial exposure to carcinogen and the manifestation of the disease. Known as the latency period, this ranges from six to 30 years. In this study, we are examining cancer cases between 1970 and 1984. While the exact time of the crucial exposure cannot be known, we can be reasonably sure that the first worker diagnosed as a cancer patient in 1970 must have had his exposure at least six years before, i e, in 1964. As such, we would have to consider the worker strength of 1964 as the base line population.

In an industry, exposure to pollutants is not uniform among all categories of workers. An estimated 20 per cent of employees who are on non-production jobs (like clerks, peons) can be classified as the marginally exposed group. The remaining 80 per cent of employees, whom we classify as the seriously exposed group are taken as the base-line exposed population.

These manipulations are not possible in the case of ESIC data because we have no way to ascertain the year of enrolment or the nature of the job of the workers who have been diagnosed as cancer. As such, we would take the entire insured workers of the respective years as the base-line population.

Since ours is a retrospective study, we are examining the mortality profile of the past 15 years. Here, we are confronted with the problem of assessing the exact cause of death. What are the sources of information from which we can obtain reliable data? Firstly, the hospitals. While some hospitals informed us that the old documents are not preserved, two major hospitals refused to co-operate for reasons known only to themselves.[7] Then we looked into the register of births and deaths maintained by the local self-governments. In many cases the cause of death has not been recorded properly. This is an all-India phenomenon. It is only recently that the Indian Council of Medical Research (ICMR) has initiated a programme for maintaining the mortality data in India according to the World Health Organisation (WHO) norms.[8] Another source could be the personal dossiers of workers maintained by the management. Even this source is not free of errors as can be seen in the ensuing discussion.

Insted of depending on a single source, various soruces as given below have been consulted so as to arrive at a near accurate conclusion. Lists of workers who died along with the cause of death were obtained from the trade unions of IRE and TCC. The cause of death was cross-checked from dossiers. Cases in which the union data did not tally with the dossier, detailed interviews of co-workers, trade unions activists, family members and neighbours were conducted.[9]

To enable comparison of the data of all the three population groups (IRE, TCC and ESIC), it has been converted into rate per 10,000. After conversion, the relative risk in IRE was estimated.[10] Statistical test (chi square) was used to see if the difference between the study and control populations is significant.

Cancer

According to the unions, 14 workers of IRE and four workers of TCC died of cancer between 1970 and 1984. As per the IRE dossiers, only eight workers died of cancer.

Out of the six controversial cases, it is impossible to accept the unions' claim of cancer as cause of death in the first three cases. In the case of one, it is difficult to arrive at a definite conclusion. The last two workers, we are reasonably sure, died of stomach cancer. This brings the total number of cancer deaths

in IRE to ten. One worker is now under treatment for lung cancer. In all, there have been 11 cancer cases in IRE since 1970.

Our data have the following serious limitations:

(a) Workers who left service since 1964 have not been followed up. Table 2 provides the service particulars of the existing workforce in IRE. Out of 471 employees, 67 started working before 1960 and another 30 joined between 1961-66. Average annual enrolment during 1961-66 being 5, there were 87 employees on April 20, 1985, who belong to the pre-1964 stock. Thirty-two workers of the pre-1964 stock are now in the managerial cadre, another 22 died while in service during 1970-1984. In other words, out of 328 base-year worker population of IRE, 187 have either resigned or retired. Of these, 140 (80 per cent) belong to the seriously exposed populaton. Since we do not know what happened to them, our result is likely to be a gross underestimation of the exact risk in IRE.

(b) The level of accuracy with which cause of death is recorded in the dossier is questionable. For instance, in one case, of death has been mentioned as "failure of heart" which is a layman's term for cardiac arrest. More revealing is the entry showing costochondritis as cause of death.

In IRE, there were four cases of stomach cancer. The remaining cases are of different sites. While radiation injury can produce malignacy of any organ, there is a strong association between certain types of cancer and occupational exposure, like lung cancer among uranium dial painters. Let us see if we can offer any explanatory hypothesis for the randomness of 'site of cancer' in IRE.

IRE has all kinds of radiation hazards, *viz*, external from beta and gamma rays, internal from ingested nuclides and inhaled radioactive gases like thoron and radon. The most serious threat in IRE seems to be from the internal emitters which are either ingested or inhaled. Now let us see the behaviour of internally deposited radioactive elements:

(a) Thoron is a noble gas (it does not react at all). It has alpha activity and a half life of 54.5 seconds. Polonium, the thoron daughter is a slid with alpha activity and a half life of 0.16 seconds. Next in the series is Thorium B with beta and alpha activities and a half life of 10.6 hours. While thoron does not react, her daughters get attached to the tissues nearby, in this case lungs. And keep on damaging the cells.

(b) We have earlier observed that all heavy metals (including the radioactive ones) follows the course of calcium. In other words, as the ageing process sets in, ingested radioactive metals settle down at soft tissues all over the body.

(c) The ITRC study quoted above reveals that thorium also settles down in testicles. Albert R E reports that workers in plants refining thorium have shown chronic deposition of the metal in lungs, lever, kidneys, spleen and bones."

All this evidence proves tht once thorium enters the body, it behaves very randomly. So does tumour. Clumps of cancerous cells, often break away from the parent tumour, migrates to new organs seed out and start growing as secondary cancers, which are known as metastases (literally, "standing in an abnormal place"). Sometimes, the primary cancers remain undetected. We have therefore taken all types of cancer (including leukemia) into a single group for the purpose of analysis.

Heart Diseases

Let us now examine the incidence of heart diseases in IRE and TCC. The method of data collection for this has been the same as that for cancer.

A word of caution—as mentioned earlier, workers of both the factories are exposed to invading pollutants from neighbouring factories. Among such pollutants, sulphur dioxide released by FACT is of more significance in terms of concentration as well as the associated health hazards. Chronic exposure to this gas leads to thickening of alveoli walls of lungs, causing respiratory diseases like bronchitis, which at a later stage can graduate to heart diseases. This disease cycle is kwnon as Chronic Obstructive Pulmonary Diseases (COPD). The incidence of respiratory and heart diseases is very high in the entire area.

All the cases of heart diseases in IRE therefore cannot be attributed to the pollution caused by the manufacturing process in the plant. Likewise, the frequency observed in TCC may not be the expected frequency in an average factory. Assuming that the pollution load by FACT is equal in both IRE and TCC, the difference in frequency between the two population groups can be attributed to the presence or absence of causative agents in their respective work environments.

The figures for IRE and TCC are fatal heart diseases. The ESIC data, which also is presented below represents the incidence only—not all of them might be fatal.

Mortality Profile

So far, we have examined the frequency of two radiation caused diseases—cancer and heart diseases. There is another group of diseases which is broadly classified as radiation-aided. We saw that radiation can also cause cell death. An absorbed bone marrow dose destroys white blood cells, which are essential for fighting infection. If cell death is massive, the organism would be rendred incapable of fighting even a very common infection.

Cell death can also lead to premature ageing. Measurement of the ageing process involves high technology gadgets which we have not been able to use. However, since the end result of ageining is death, consideration of the total mortality profile might reveal certain basic trends. Let us compare the total mortality (due to all causes other than suicide and accident) in IRE and TCC. (Mortality data pertaining to workers insured under ESIC is not available.)

In order to facilitate comparison between units, data presented earlier has been converted into rates per 10,000. Relative risk between IRE and TCC for cancer and heart diseases is 4.62 and 2.24 respectively. Coming to total mortality, IRE workers had 2.72 times greater risk of dying of all causes. More pronounced is the relative risk between IRE and ESIC which is 6.77 and 2.72 for cancer and heart diseases respectively.

How significant are these differences? In the case of cancer, difference between IRE and TCC/ESIC is statistically significant at 0.01 level. For heart diseases, while the difference between IRE and TCC is significant at 0.2 level, the difference between IRE and ESIC is significant at 0.01 level. Difference in mortlity due to all causes between IRE and TCC is significant at 0.01 level. In short, we can conveniently reject the null hypothesis.

Genetic Disordes and Infertility

During the course of the study, we also stumbled upon a few cases of sterility among workers and genetic disorders among their offsprings. The data is not comprehensive. Major reasons for limitation in data ae as follows:

(a) Most diseases of autosomal dominant variety manifest themselves at a later age. The parents do not perceive such cases as genetic.

(b) A welfare measure in IRE has not made any survey (with limited resources) of families virtually impossible. IRE is one of the few industries in India which has a unique housing scheme. An employee can build a house with a liberal loan from the company at a place of his choice. Since every worker with a minimum of ten years of service can own a house under this scheme, the unions did not press for a housing colony. Some workers in IRE feel that the liberal scheme was introduced for concealing the increased incidence of genetic disorders among the employees' offsprings. Incidentally, the scheme was introduced a couple of years after the health physicists' team took position in IRE.

Among the affected workers, one in three alone presented the children before a medical board, consisting of three doctors of Lissie Hospital, Ernakulam. The board ruled that the cases can be attributed to inbreeding.

There are two types of inheritance of genetic disorders—autosomal dominant and autosomal recessive. In autosomal dominant inheritance, only one of the parents supply a defective gene, while in the recessive inheritance, both the parents supply the defective gene at the same genetic locus. The 'book' has the following to say on the nature of inheritance:

> In as much as recessive diseases require the inheritane of a mutation at the same genetic locus from each parent, when the genes are rare, the likelihood of any two parents being the carriers for the same defect becomes small. However, if the parents have a common ancestor, and if that ancestor was a carrier of the recessive gene, then the likelihood that two of the descendants have inherited the gene becomes relatively great.[12]

A person who has inherited a defective gene which lies dormant would not be affected by the disease. He or she is called a carrier. When two carriers of the defective gene at the same locus mate, the statistical probability of inheritance is:

> twenty-five per cent of the children will be normal, 50 per cent would be heterozygous carriers and 25 per cent would be homozygous and affected with the disease . . . Since with recessive inheritance, only one of the four children in a sibship is expected to be affected, multiple cases in a family might not occur.[13]

In the case another worker, all the four children have been affected. Moreover, according to the worker, he and his wife are sixth in a chain of consanguinity. This introduces an increased possibility of some other relatives also being affected. No one has been, so far. Secondly, as the provisional diagnosis shows, all the children do not share the same symptom complex or clinical history. This suggests the possibility of damages at different genetic loci. Hence, the probability of both the husband and wife carrying several damaged genes seems to be extremely remote.

Infertility

It is not possible to assess at this stage whether all these cases are radiation-related. If they are, then the situation in IRE would have historical significance. IRE, in that case would be the first reported nuclear facility in the world to cause radiation-induced sterility among workers.

Cases of sterility deserve a closer examination. In the survey of literature, we saw that unlike cancer and genetic disorders, sterility is a non-stochastic effect which has a safe threshold. Since there is no history of radiation-induced sterility among males, the exact sterilising dose is not known. Sterilising dose for females is 700 rems, administered during a short span of time. Since overies are more protected than testicles, male sterilising dose should be lesser than that of females. One estimate places the dose at 60 rems. Assuming that the workers became sterile during the first twelve years of their service, the annual average exposure works out to 50 rems, which incidentally is ten times higher than the maximum permissible limit.

Health and Safety Apparatus

HPD of BARC is responsible for monitoring the health of workers in all DAE undertakings. Health physicists were posted in IRE, Alwaye, in 1962, ten years after the factory went into stream. In 1966, the team recommended a few safety steps, like rotating workers from spot to spot after a fixed interval, provision of gumboots and rubber gloves, etc. HPD is supposed to monitor the dose absorbed by workers and take remedial action in critical cases. Monitoring is done by analysing the film badges worn by workers. Film badge analysis alone is not adequate in an industry like IRE where the major hazard comes from radionuclides and radioactive gases like redon and thoron. A near accurate account of the dose absorbed can only be made through analysis of biological samples which is not being done in IRE. Even the results of film badge analysis is not communicated to the workers. Similarly, HPD had conducted a chromosome analysis of Alwaye workers during the late seventies, the result of which has also not been communicated so far.

In the past, three workers were transferred to less hazardous jobs because of adverse medical findings. In these cases, the workers who had got medical advice from private practioners had to fight their way out for transfer. HPD, rather than assisting in such cases, strongly opposed the transfers. Even though all workers suffering from occupational diseses are entitled for compensation under the Workmen's Compensation Act 1923, no one in IRE has got it so far. In short, there is nothing much to comment on the health and safety apparatus in IRE.

Chromosome aberration, chemical change of DNA and cell death are the immediate cellular responses to an absorbed dose of radiation. The end result could be any of the stochastic or non-stochastic diseases mentioned earlier. In this paper, we have been able to demonstrate statistically significant differences in incidence of cancer and mortality due to heart diseases and all causes between IRE workers and control populations. The incidence of sterility among workers and genetic disorders among their off-springs reported above is seemingly higher than their spontaneous occurrence in general population.

A retrospective epidemiological study of this nature, can only formulate clinical hypothesis. At best, one can state that the study population was exposed to the agent under consideration during the reference period—in this case till 1964. Incidentally, two years after this, the so-called control measures were introduced in IRE an HPD. How effective are these measures? To obtain an answer through an epidemiological study, one would have

to wait a few more years. Fortunately, we have a little more concrete evidence. In 1978, BARC conducted a chromosome study of IRE, Alwaye, workers. Though the results of this sutdy are yet to be published, there is a reference to this one of the DAE annual reports:

> In continuationof the efforts to evaluate the biological effects of high background radiation on human population residing in the monazite belt (Chavara, Neendakara in Quilon district, Kerala), chromosome analysis was carried out on 179 samples.
>
> Under our chromosome analysis programme, broad sample in the normal background areas were analysed. Data on newborn and their mothers did not indicate any differences in the chromosome aberration frequency between samples from normal background radiation areas and those from high background radiation areas.
>
> In the samples taken from the IRE workers at Alwaye, a high abberration frequency was indicated than that observed in the high background radiation, Chavara and Manavalankurichi samples.[14]

In short, workers' health was, and still is in jeopardy.

During the course of our study, we also found that there are gross irregularities in the fields of radioactive waste management, as well as storage and transportation of radioactive materials—issues which are beyond the scope of this paper and hence being reported separately.

The situation is alarming. This calls for immediate action. The management of IRE has agreed to palliative measures like scanning of all workers for tumour by the Cancer Detection Centre, Cochin, which is not enough in a hot spot like IRE. The need of the hour is a comprehensive, interdisciplinary study of the plant and the workers. In order to take effective remedial action, there should be a health survey of the workers which should include analysis of urine, blood, chromosome and tissues of critical organs like gonads. The workers who have absorbed dose above the permissible levels should be removed to safety. In the case of work environment, activity status of each spot would have to be measured and engineering measures adopted.

Such a study should have representation from the workers as well as the people because what at stake is not only the health of over 500 employees, but also the national gene pool which the present decision-makers have no right to tamper with. We do not own the gene pool.

A clear understanding of the exact magnitude of hazards posed by IRE assumes national importance at this juncture of our history. IRE is the only DAE venture which has completed 30 years of operation, which incidentally is the average latency for cancer. Today, DAE is pushing forward its ambitious plan which involves a tenfold expansionof nuclear electricity generation by 2000 AD. Before allocating a massive Rs 22,177 crore from the public exchequer for the planned expansion, people have a legitimate right to look into the track record of DAE during the past three decades of its existence.

[This report is part of a book which is now at the design stage. This study is a joint venture by the trade union activists of IRE and TCC, Forum for Occupational Health and Environmental Studies, Alwaye, E P Mohanan and a group of students of Medical College, Calicut, and Krishnamohan, a scholar of environmental science at Jawaharlal Nehru University (JNU), New Delhi. The team acknowledge guidance and help by Gyanesh Khudaisya, D Banerji and Imrana Quadeer of JNU. Fraternal assistance from Nikolai Izmerow, Director, Institute of Industrial Hygiene and Occupational Diseases of the Academy of Medical Sciences of the USSR, Moscow, Ralph Nader and Joan Claybrook of the Critical Mass Nergy Project, Washington, and Anthony Mazzocchi, Directpr of Health and Safety, Oil, Chemical and Atomic Workers International Union is gratefully acknowledged.]

Bombay's Health Priorities

A LONG-STANDING criticism of health services, curative and preventive, private and public, has been that they are heavily urban-oriented and are skewed to offer the least assistance to those who need it most, the rural poor. What is often not as well documented is that the distorted priorities also influence urban health care. The annual budget estimates of the Bombay Municipal Corporation (BMC) recently presented provide a glimpse of just how efficiently the civic body is discharging its obligations of providing health care.

The corporation spends 29 per cent of its revenue budget on public health and medical services. Expenditure on health care has been steadily increasing—there has been a 69 per cent increase in the last three years. What is important, however, is that most of this increasing expenditure has been on the curative side. The health budget comprises three components—public health, medical relief and education, and measures to control environmental pollution. The proportion spent on public health has consistently, even if marginally, decreased—from nearly 15 per cent in 1977-78 to 13.7 per cent. A grave result of this is that neither the infant mortality rate nor the overall death rate has shown an improvement in ten years. Pollution control which includes such activities as air quality monitoring, research laboratories for analysis of pollution as well as an enforcement wing for ensuring the implementation of control measures, accounts for less than one per cent of the expenditure. Admittedly, the allocations in this area have increased many times in ten years, but considering that the BMC's own health survey has shown a definite link between the prevalence of a large number of health problems and air pollution, should this area not have been considered a priority area in health?

The corporation appears to be attacking the problem of health from the wrong end—waiting for people to fall ill so that they may be taken care of, instead of eliminating the root causes of ill health. The corporation is not alone in its apparently muddled understanding of these issues—every government, state and central, has followed the same principles of neglecting preventive health care. The reasons are, of course, obvious. The creation of imposing hospitals equipped with new equipment (even if they are ever put to use) adds to the prestige of the authority even as it offers temporary 'repair facilities' for the masses. However, expanding public health measures is quite another matter. In doing so, the state will necessarily have to confront the very classes which sustain it—whether it is a matter of properly distributing clean water supplies or bringing defaulting industries to book.

Even within curative health care, the services are so created as to provide the least access to the working masses. Hospital beds, for instance, show such a skewed distribution. In 1980, 60 per cent of the hospital beds maintained by the corporation were in city wards in south Bombay comprising 35 per cent of the largely better-off population; the civic body did not maintain a single bed in the area which 'houses' a large proportion of the working class population of the city. To make matters worse 67 per cent of the government beds are also in these south Bombay wards. The rest of the population (the lower middle class and working class) is forced in the city to depend on private medicare. Although the number of hospital beds has gone up since then, the situation is hardly better. As the municipal commissioner has pointed out, "we have undertaken the construction of many skyscrapers for increasing the number of beds in our major hospitals . . . while a large suburban population is denied immediate access to primary health centres".

Quite obviously, whatever the increases in the health budget, it is unlikely to benefit the urban masses. In fact, what with the commissioner's proposal to hike hospital registration charges, "restricting use of costly medical equipment" by introducing "reasonable charges" for their use and "avoiding waste of medicines and diet", users of municipal facilities will find the services gradually moving beyond their reach.

PP

Ruins of War

LEBANON is constantly reported for internecine fights, the shifting loyalties of the groups involved in the fights and above all Israel's repeated invasion of that country, the latest being in 1982. In the din of all this gunfire and among the ruins of war, the condition of millions of Palestinian refugees in Lebanon and in Israeli occupied territories of West Bank and Gaza has almost been forgotten. War itself has become an epidemic in the region and its impact on people's health is of epidemic proportion.

The fighting between the Palestinians and other armed groups which are from time to time supported by Syria, Israel or Iran, has almost destroyed the whole social fabric, and as a consequence even the health care services, in the Palestinian refugee camps. Even the abysmal health services which were available to them before the 1982 Israeli invasion of that country have almost ceased to be. For the last two years the Syrian-backed Amal Shite Muslim

militia has resorted to intermittent seizure of Palestinian refugee camps and thereby cutting the residents of all civil and medical supplies.

Chatila camp has been reduced to rubble and its population have fled south in search of food and shelter. In Bourj-al-Barajneh camp 35,000 people along with the British charity, Medical Aid for Palestinians are trapped. The electricity and water supplies to the camp are cut-off by the Amal militia. Food supply is not reaching the camp people. Anybody coming out in the street to get water and food or trying to leave the camp is shot dead. All relief supplies are turned back by the militia. Much of the medical facilities established by the MAP at the cost of £ 30,000, after destruction in the 1982 war, in the Gaza hospital, are destroyed including the hospital building itself. Another remaining hospital, the Haifa hospital, has lost two of it's there floors and there even medical worker's and patients have been hit by sharpnel. Because of such attacks on all these camps, it is estimated that almost 2000 camp inhabitants are killed, 4500 wounded and 80,000 made homeless.

Double Standards: Some Improvements

In the past dozen years, major pharmaceutical firms have made substantial improvements in the way they label and promote their products in the Third World. They are now less likely to puff up their claims to physicians and are more willing to disclose possible serious or lethal adverse reactions.

These are the findings of three researchers at the University of California School of Medicine in San Francisco (UCSF)—Milton Silverman, Philip R Lee and Mia Lydecker. This group pioneered comparative marketing studies beginning in Latin America in the early 1970s. Their latest findings were published in the October 1986 issue of the International Journal of Health Services.

Their original survey covered 147 products marketed in the United States, Mexico, Central America and South America and the results were published in 1974. In their second study, published in 1982, the UCSF group covered 515 products marketed in the United States. Latin America, Central Africa and Southern and South East Asia. Their present investigation includes 1,069 products marketed by about 300 companies in the United States, the United Kingdom and 28 developing nations.

The present study reports striking changes. Many of the firms were 'found to be showing more restraint in limiting their claims int he Third World to those which can be supported by scientific evidence and were far more willing to desclose serious hazards'.

In the case of dipyrone, a widely-used but reputedly dangerous remedy for fever and pain, itw as noted that 119 of 155 products now carry warnings of possible fatal blood damage. This represents a marked improvement over the situation in 1974 and in 1982. Most of the products still without such warnings were found to be marketed in India, Mexico and Central America, mainly by American and West German firms.

Of the 12 aminopyrine products, used for the treatment of fever and pain, seven—marketed by Polish, Spanish, Swiss and German firms—carried no adequate warnings of possible blood damage. Of the 15 phenacetin products which are used to control fever and pain, eight carried no warnings of possible kidney damage. They are marketed by American and German companies. All three of these products have long since been banned from the United States and the United Kingdom.

In the case of chloramphenicol, a valuable but potentially dangerous antibiotic used especially in the treatment of typhoid fever, 93 of 103 products now list warnings against use in trivial infections, against preventive use and against prolonged use. This too represents a remarkably improved situation. Nevertheless, some firms were found to be promoting chloramphenicol products in Indonesia, the Philippines and Thailand for such a minor illness as tonsilitis.

Similar improvement was noted in the promotion of tetracycline and other antibiotics, tranquilizers, anti-depressive agents and anti-arthritis drugs.

Silverman, Lee and Lydecker also examined the promotion of numerous 'sex tonics' in the Third World by various American, European and Third World compaies. These are widely recommended and sold for such indications as premature aging, sexual weakness, lack of physical and mental capacity, failing memory, fatigue and 'general wearing-out phenomena'. Evidence to support such use is questionable at best. None of the products is allowed on the market in the United States or Great Britain.

Drug companies cannot explain away these differences merely by claiming that the laws of a specific developing nation dictate what may or may not be put on the label. In the same country it was obvious that some brands of a particular drug carry detailed warnings, while other brands of the identical drug carry no warnings of any kind. Among the companies whose products were examined, some were based in capitalist nations, some in Marxist-Socialist countries and some in the Communist bloc. 'Our data show no significant differences between them inthe reliability of their promotion', the USCF team said. Among the profit-making companies, some were multinational while others were domestic or national. 'Our data indicate that most cases of irrational promotion involve domestic firms in the Third World'.

Community Participation in Integrated Child Development Programmes

The Kerala Experience

v raman kutty

This paper, attempts to enumerate the obstacles that stand in the way of community participation in Child Development Programmes, drawn from the experience of Kerala state in India. There is also an attempt to provide a conceptual and theoretical basis to the need for community participation in health programmes.

IN this article I shall attempt to discuss some of the issues related to community mobilisation for action in child development programmes. The first part of the paper shall delineate the conceptual or theoretical basis for the need for community participation in child development programmes; the second part shall be devoted to examining some of the experiences in the light of these.

The first major task in such an attempt is to define the nature of child development programmes. Child development programmes grew out of two ideas:

1. The realisation that the development process has to be seen not just in its economic perspective.

Rajni Kothari says: "I suggest that the unidimensional and almost exclusively economic basis of the development paradigm has undermined the prospects for not just development, but for the sheer survival of large strata of the world's people. Mere transfer of resources and technology does not necessarily bring us any closer to the realisation of a desired state". (Kothari, 1985).

Among these 'extra economic' goals of development, child survival should certainly demand high priority. "High rates of infant and child mortality are one of the heavier burdens borne by the populations of the less developed world". (Barnum and Barlow, 1984). Hence even from an economic point of view, investment in child services—for health, literacy, and in general better quality of life for children—have returns in terms of quality of personal in later years that justifiy the investment.

2. The second idea—closely related to the first—is that of an integrated package of services for children. Most of the services offered have nothing now in their content: be it immunisation, supplementary feeding, promotion of breast feeding, or informal education. What is new is the integrated approach in supplying these services. But it should be realised that ". . .true integration must mean something other than the simplistic invitation of everybody professionally concerned with a problem, to do what they are used to doing in their sector specialities, with the only difference that they do it simultaneously". (Kunttson, 1985). Thus integration itself is to be seen as a strategic move, a specific input into the defence against deprivation.

The Child Survival and Development Revolution (CSDR) as envisaged by the UNICEF could be described as the fomalisation of all these ideas. The CSDR is—or should be—the ultimate goal of the integrated child development services initiated by many of the developing countries including India. But it should be understood that it is difficult to separate the process and the goal in this: the CSDR is both the objective of the programmes as well as their organisational content. The CSDR be said to be characterised by three principles in its organisation, each of which underscores the importance of community participation for its success:

(1) The 'demand based approach' to child health

(2) Low cost interventions that can be afforded by the poorest of communities; and

(3) Approaches with minimum technological complexity, so as to encourage self reliance. I shall examine each of these in detail.

The Demand Approach to Child Health

The central idea behind the concept of the CSDR is to enable parents to protect their children from preventable death and disablement: and the thrust of the strategy is to convert 'latent demand into effective demand' for child health. (Vittachi, 1984). What is the concept of demand for health? For economists, the demand is the "ability and willingness to pay". (Fuchs, 1968). Paying may not be always in terms of money. In an under-developed community, even when services are supposedly free, mothers have to forego one day's work to avail of these services, because of so many reasons that I need not go into. The value these sometimes illiterate and mostly formally unemployed women place on their time, is the cost of the service. In terms of relative value to the family earnings, this should be certainly a high value. The demand approach to child services in underdeveloped communities should mean, if successful, that mothers, who are the key figures in caruing for the children, are prepared to incur this cost in order to avail this service. Thus we see successful demand oriented programmes have a built in element of community participation.

But it is often not realised that what is demanded is not what is needed. The health or development needs of a community are those defined by the expert as those required for them to reach a certain predetermined level of development. In an ideal situation, health demands coincide with health needs. But more often, health 'demands' are in excess of or totally different from, health needs. There are two types of problems arising out of demand: demand failure and inappropriate demand. Demand failure in the context of child survival strategies means that mothers do not come forward to seek the protection of available services like immunisation, oral rehydration, growth monitoring, and even curative services. This problem is common in developing com-

munities, and is in turn due to two reasons: the illiteracy and ignorance of mothers and their lack of self confidence in decision making roles about children, which are themselves related problems. The second demand problem, that of inappropriate demand, is more common in developing communities like Kerala, where under the influence of high pressure advertising, educated but poor mothers reject cheap but effective alternatives and go in for child health inputs like milk foods, weaning foods, and tonics which they can ill afford. Both these problems, insufficient demand as well as inappropriate demand, exclude community participation in child development programmes: the first because people do not come forward to take part in the programme, and the second because they seek solutions elsehwere.

Low Cost Intervention

The second point of stress in the CSDR, and also important in ensuring community participation, is that the interventions suggested are less costly, which can be afforded even by the poorest community. In fact, "voluntareeism or community contributions are a necessary element in the cost structure if the programme is to be maintained on a national scale". (Nyix, 1984). We should define what we mean by 'cost'. What is apparently 'low cost' in terms of rupees and paise may be high cost in terms of time spent to a rural mother in a developing community. Here again, it is important to understand that in such a situation, community participation is one thing that can make costs less.

Inputs of Low Technology Complexity

The third point of emphasis is that the suggested interventions have very little technical 'density', in the sense of needing trained personnel and sophisticated equipment, in spite of being the fruit of modern thought. In fact, among the four key strategies currently emphasised in the CSDR—growth monitoring, oral rehydration, breast feeding and immunisation—the only intervention with any technological sophistication is immunisation. The central idea is that instead of becoming complex tools in the hands of experts in respective fields, these techniques become effective weapons in the hands of the community to combat threats to betterment of children's conditions. Thus theoretically, this should also have a strong component of community participation.

There are two reasons why I have gone into some detail to show how the child survival and development revolution is built around concepts which essentially entail community participation, by their very nature. The first is to build a conceptual background against which I shall examine some experiences with child development programmes. The second and the more important reason, is to make the point that while the three aspects discussed: demand orientation, low cost, and limited technology, are necessary conditions for community participation, they are not sufficient. If community mobilisation is to be truly effective, there should be a really participatory role for the beneficiaries at every stage from planning to implementation. I shall come back to this point in the last part of this paper.

In this part there shall be an attempt at examining some of the bottlenecks to community participation from experience of child development programmes in Kerala. We have witnessed a series of programmes operating at various stages, fulfilling different needs in child survival and development norms. The two programmes which shall be discussed here are the (i) the Composite Programme for Women and Preschoolers, which was in operation through balwadis (children's centres) in Kerala. Here the development department of the government of Kerala in conjunction with the health department, provided an integrated package of services to preschoolers and pregnant and lactating mothers. (Government of Kerala); (ii) The Integrated Child Development Services Scheme of the government of India. It was launched in 33 community development blocks all over India in 1975, and consequently grew to 300 blocks by 1981. In 1982 the ICDS was included as the principle vehicle for meeting the needs of children and their mothers under the twenty point programme of the prime minister. (Sadka, 1984).

Demand need variation: One of the most important flaws cramping the execution of such programmes is the design which is decided centrally and is usually inflexible. It is not often remembered that child survival goals, and hence demand as well as need differ widely in India, among states as varied as Kerala with its low infant and toddler mortality to that of Uttar Pradesh, which would approximate to the all India picture in these indices. Unfortunately this factor is not given due consideration in the programme, and the goals and style of functioning are decided without taking into account the regional differences in child survival and development priorities. As a result, aspects of the programme which are very relevant to some areas are totally irrelevant in others, and consequently cannot attract people's participation. This is a price we have to pay for inflexibility. Kerala being a state where the demand for formal education is very high, the age of school entry is five years, and pre-primary education is very much in vogue, it is not surprising to find many rural areas where even poor mothers are reluctant to send their children to the ICDS after four years. But in a state with a poor level of formal schooling, the non-formal education imparted in the ICDS centre till six years may be an important input which cannot be ignored.

Rigid structure: The second and very important aspect which precludes community participation is the rigid nature of the programme implementation. The beneficiaries have no role in deciding the site, or number of functionaries at the local level. Here it is interesting to contrast with the CPWP programme which is now being eclipsed by the ICDS. The design of the CPWP was such that in each area, the people had to form and register a mahilasamajom (women's club) which had to provide the building, premises and local level functionaries for supplementary feeding and other child development programmes. There was also an attempt to provide the local type of food and grow some of the vegetables in the premises, coupled with many employment generating activities for women, like goat rearing etc. This character of participation has been lost in the design of the ICDS. This

is also a particular example of the point raised earlier, i e, whereas in other states of India one should not expect women to take the initiative to run their own community development programmes, and hence a government administered programme might perhaps act as a focus for initiation of such activity, the opposite is the case in Kerala. In Kerala women do have the confidence and initiative to run these programmes, perhaps borne of their better literacy and exposure to media, and as such the programmes should be sufficiently flexible to allow their participation. This would be expected of a demand-based approach, and would simultaneously ensure community participation.

Goals for beneficieries and goals for functionaries: The point is again related to the first two. When a programme becomes centrally administered with a fixed pattern and permanent staff, it is inevitable in the long run that the executives of the programmes, on the whole, put their own personal goals first. This is a folly to which it is particularly susceptible in Kerala with its large number of educated unemployed. While it should not be grudged that such programmes have provided jobs for a number of youth it should not also be forgotten that furthering their career opportunities is not the primary aim of the programme. This point has been at the back of many recent incidents in Kerala. This is an area of conflict, which, unless resolved, effectively blocks people's participation in the programme.

Not identifying priority needs: Sometimes a community may be badly in need of a service, like protected water supply, or irrigation facilities, which, while not directly linked to child health needs, can act as a rallying point from which child development services can reach the people. Unfortunately, this aspect of community development has not been given its true importance in the programme. This is another obstacle on the way to better community participation.

Emphasis on technical aspects: There is a tendency on the part of the experts concerned with planning and implementation of the programme, especially medical personnel, to see it as exclusively a technical programme. Doctors connected with the programme should be disabused of the idea that it is a medical programme. On the other hand it should be seen as a non-medical programme with health returns. From the side of beneficiaries, there is a tendency, at least in Kerala, to view the ICDS as a formal preschool education. This is to be expected in a state where mothers put such a high value on formal education even at the pre-primary level. Here again, it is an instance of demand conflicting with need, and unless people are properly appraised of the objectives of the programme, there is a danger that they shall be disillusioned and this will effectively block their participation.

Using the programme for political leverage: It is inevitable in a highly politically-conscious state like Kerala, with political fortunes see-sawing, that programmes like the ICDS are used for political advantage. If this should happen, it alienates a large section of the community and this works contrary to the spirit of community participation.

In summing up, I should point out that child development programmes indeed have a large potential for community participation in their design and execution. In our experience, a large part of this potential is fulfilled. In fact, it would not be wrong to state that the ICDS is one programme in in the state with a large element of community participation even as it stands now. I have only tried to point out areas of conflict, the resolution of which is a must if we are to go further.

Coming back to conceptual basics, community participation in child development programmes fails if community participation itself is not seen as a primary objective. Participation should not be a means to facilitate reaching other goals. On the other hand, maximising community participation should be the primary objective, subject to the constraints. If this approach is adopted, reaching the other goals will be much faster and automatic.

nuclear mind-set of those who are in a position to take crucial decisions concerning nuclear war and the arms races.

While local and regional peace movements can play a vital role in promoting the *process of disarmament and sustaining its momentum, a world completely* and *permanently* safe from the fear of nuclear weapons cannot be created by movements against nuclear weapons alone. Such a world requires transcending nationalism and national elites in the name of the universal interests of human kind. In short the struggle to create a truly and permanently nuclear free world is an intrinsic part of the struggle for socialism. Without a nuclear free world there will be no socialism. Without socialism there will be no nuclear free world!

Milk Monitors

pauline jackson

Methodologies for the Study of Low-Level Radiation in the Midwest, Charles Huver *et al*, Millville, MN, Anvil Press, 1979, $ 5.

THOSE who seek an easy introduction to the dangers of low-level radiation would do better to read the pamphlet-length summary of this book, *Nuclear Waste - The Time Bomb in our Bones.* Yet this extraordinary book is undoubtedly a landmark contribution to the debate over nuclear health hazards. It is a product of detailed investigation by a team working with Land Educational Associates Foundation Inc. (LEAF), a citizens' research and resource network who publish books, newsletters, engage in lobbying and popularise research findings for anti-nuclear activists.

This book appears to be their most ambitious attempt yet to take on the state at its own game: the monitoring of low-level radiation releases and their impacts on human beings. Their work is intended as a critique of the U.S. Environmental Protection Agency, the U.S. Atomic Energy Commission and those private or public agencies who, in the opinion of the authors, downplay the hazards of low-level radiation. Their starting point, therefore, is an alternative method of monitoring the results of low-level radiation release, to combat the defects, errors, inadvertant omissions and mistakes of official monitoring.

Their approach assumes that the problems surrounding monitoring can be reduced to precise errors, definite defects, certain omissions and accidental mistakes - an assumption that is far from proven in the book. Certainly, the authors succeed in revealing an inadequacy of corporate and state monitoring. But they present the inadequacies more as a series of random and accidental oversights than as a concerted strategy by supporters of the nuclear industry to misinform the public.

Huver *et alia* are critical of monitoring methods but not of monitoring as such. They would not go so far to argue monitoring for low-level radiation (or low-level toxic chemical exposure) has become a fetish of the chemical and nuclear industry, used to lull the public into believing that a quantifiable measurement is equivalent to quantifiable control over releases (as argued by Levidow and Pomata in *RSJ 9*). On the contrary, the authors accept monitoring and seek its extension and perfection by a more sensitive, all-encompassing methodology.

To illustrate their perspective: an example cited in the study is the frequent use by nuclear proponents of the idea of 'the average dose' of low-level radiation, which gives an 'average' population a once-off hit of radiation and then allegedly disappears. The authors expand at length on the inadequacy of monitoring which fails to test for the consequences of all 189 radionucleides which can have an impact on health, with tragic consequences in cancers of specific organs of the body of individuals. The monitoring of selected radionucleides can be attributed to an inadequate methodology, or it can be conceptualised as a deliberate attempt to conceal health hazards, that is,as a political choice by state and corporate scientists to hide health risks from the population. If all 189 radionucleides were monitored and the results rendered public, this would imply that the nuclear industry and its state supporters did care about health - an assumption that proved fatal for nuclear activist and trade unionist Karen Silkwood, who was assassinated while attempting to prove the hazards generated by her own nuclear workplace.

The LEAF study provides some useful insights into milk monitoring techniques. Milk monitoring had been going on for years in Wisconsin, where the research team was based, so records of the results were available from various monitoring stations over a period of years. Examining the records, they found evidence of radioactive substances which could only have come from atomic fallout during the 1950s. Matching the peaks and drops in measurements with information in tests carried out in the atmosphere, they demonstrate the continuing impact of radiation on a population who were perhaps only children at the time of the test. They suggest a method of calculating the half-life of radioactivity still in the bones of adults who were exposed at the time, and who would be vulnerable to cancer today.

The authors were surprised to find that the records were blank for considerable spans of time. In some records, the same results from monitoring appear on consecutive readings, from which they surmised that NO monitoring of milk had been carried out during certain periods, while on others the results of the preceding tests were copied into the records. In addition, monitoring results of *no* radioactivity were to be found in the Wisconsin records. This provides the authors with an occasion to disect some arguments around 'detectable levels' of radiation. In this regard they remark: "...it is obvious that realistic dose estimate cannot be attempted by assuming that concentrations below a "detectable level" must be interpreted as meaning that absolutely NO iodine-131 is present" (pp. 61-62).

The statement reveals a weakness in their analysis of the purpose of monitoring in the first place. If the purpose of monitoring were to reveal the presence of radioactive substances in the milk, exact and precise measurements (however miniscule) would no doubt have been recorded. If the purpose of monitoring is to detect low-level radiation at and above the 'safe' threshold levels, then there is no need to record tiny amounts of radiations, since such tiny amounts are presumed by the monitoring agencies to be safe. The milk monitoring records which appear so defective in the eyes of the researchers are undoubtedly very adequate from the standpoint of the agencies doing the monitoring, since the test results conform to their intention in monitoring: to prove

that radioactivity in milk is not at harmful levels... levels being the crucial word!

Not content with combing the state's radiation monitoring records for faults, the authors compare nuclear reactor manager and state interpretation of the results with their own interpretations. They note that nuclear reactor utility managers and owners managed to underestimate the results of the monitoring by half. The researchers attribute this underestimation to the use of formalin, which reduces the detectability of the radionucleide Iodine-131. Being cynical, one could also attribute the underestimation to dividng the original results by 2...

The study is extremely useful in its treatment of the food cycle and low level radiation exposure; this is perhaps the best section of the book. The authors insist on the importance of the food chain as a pathway for low-level radiation ingestion. The researchers examined the dietary patterns of the Wisconsin population, including the diet of so-called minority groups. In an implicit critique of the 'average' population perspective, they detail the differences in life-style among the Wisconsin population and the accompanying variations in eating and shopping habits. They calculate the predominance of dairy products in the eating patterns and then break down the dairy products according to whether or not they were extensively processed. They propose that those who eat processed (as opposed to fresh) dairy products were less likely to get radiation exposure, since the half-life of the radioactivity in fresh milk, for example, had had more time to decay during the processing.

If one hadn't been turned off dairy products by this stage, worse is to come in their assessment of other food products. The consumption of wild berries, foods growing in marshy areas and wild venison were extremely popular in Wisconsin. The topography of Wisconsin—with its snowfalls and extensive marshy, lichen and moss-maden lands—is apparently conducive to the establishment of radiation pathways. Animals and foods with their sources in these terrains are more likely to 'carry' radioactivity from previous fall-out than other foods. Poaching of venison is so popular as to make venison a staple diet for many Wisconsin families; the deer graze on the marshy lands close to the areas of the state with the highest concentrations of Wisconsin residents who are either vegetarian, fresh-food conscious or opposed to processed food, the authors point out the radiation hazards of diet containing berries, unmilled grains and soyabean. Not even sunflower seeds escape their scrutiny as concentrators of Strontium-90! Combining factors - of diet, age, proximity to nuclear reactors, waste facilities for reprocessing nuclear materials, age when testing was being undertaken - the authors attempt to devise a methodology for examining the radiation exposure already received by the population of Wisconsin and the amounts that are still decaying in their bones from previous exposures as the half-life of radioactive substances continues to decay over decades. Their methodology resembles that used in sociology and psychology for multi-variable factor analysis.

In the absence of a chapter presenting the authors' scientific assumptions or philosophy of science, the reader is obliged to deduce for her/himself where the authors stand on monitoring, research methods, source credibility, statistical methods and so many other fundamental issues. One can draw some conclusions from their concern to enlarge the numbers of radionucleides and radiation pathways which are submitted to monitoring and their interest in the impacts on individuals in specific geographical zones, districts with distinct living and eating patterns. Their work rejects hypothetical models of the impacts of low-level radiation on 'average' populations and attempts to reconcile multiples, types and volumes of radiation emissions with groups living in their path or liable to consume radioactive contaminated foods along their pathways. Put another way, the authors reject a robotic conceptions of human beings - robotic in the sense of each person being an exact replica of the next in history, culture, lifestyle, age and so on. Instead they are attempting to humanise monitoring methodologies, to give them relevance to local communities, such as those living in the various counties of the State of Wisconsin.

It is to the credit of LEAF that they responded quickly to popular demand by publishing in pamphlet form a most readable summary of the book: *Nuclear Waste - The Time Bomb in our Bones.* Besides this 16-page cheap version of the book, LEAF have 3 informative brochures presenting the salient aspects of selected pieces of their research, aimed at Wisconsin's commune and health-food population. These formats - pamphlets and brochures - show that LEAF is capable of citizen research which unites grassroots activists and researchers into dialogue. It is all the more surprising, therefore, that *Methodologies* does not rise to the same standard of accessibility as thier other publications.

It is all the more important to have an accessible presentation of their philosophy of science when one realises the conclusion that Huver *et alia* draw from their research. They predict that Wisconsin 14 year-olds have an increased risk of cancer from just 3 radionucleides in their food - a risk double or more than the normal cancer risk. They predict that 14 year-old Wisconsin girls have an increased risk from all cancers equivalent to 25 per cent above the normal cancer risk. The authors remind us:

> Some of the Strontium-90 that found its way into baby's milk bottle in the early 1950s is still in the cells of that individual. Every year it delivers an additional 'annual' dose. Every year it increases that individual's risk of cancer (p. 168).

The risk of cancer and the suffering it implies for individuals is all the more astounding when one considers that, by the time these 14 year-olds become middle-aged, they may never have been near a nuclear reactor, may live on another continent, may never have worked in the nuclear industry and may imagine themselves safe from exposure. LEAF is saying that the damage has already been done. Low-level radiation is inside the environment of Wisconsin and cannot go away. In the words of the authors:

> It has been 'lost on the way to the bank' - it is irretrievable - it will never be safely contained in some ultimate waste storage repository. It will inevitably affect the health of individuals in the Wisconsin case study and others yet unborn (p. 179).

For authors of *Methodologies* there is no 'return to normality' after a reactor closes down or after testing halts. Low-level radiation still continues its assault on the cells of in-

dividual humans. For this protracted notion of war against radiation hazards, this book's contribution to the literature on low-level radiation is a welcome addition. For those who seek a critical analysis of monitoring as a tool for politically cooling-out agitated residents and citizens, this is not the text to peruse. But it could serve as a useful reference source for the wider debate about disinformation techniques employed by the nuclear industry and its supporters.

Hunger and Myth of Plenty

bernard d'mello

Empty Stomachs and Packed Godowns: Aspects of the Food System in India by Bharat Dogra; published by Bharat Dogra, D-7 Raksha Kunj, Paschim Vihar, New Delhi 110 063; 1987, pp VIII + 126, Rs 50.

THE stock of foodgrains in India has increased from 11.7 million tonnes in 1980 to 29.2 million tonnes in 1985. However, this huge stock of foodgrains is not an indication of plenty. Rather, it is one of the symptoms of lack of purchasing power of the poverty stricken millions who suffer from hunger and malnutrition. Bharat Dogra, a free lance journalist, presents a radical outline of the food problem in India.

More than 70 per cent of rural households lack the means to avail of even the least-cost balanced diet as recommended by the Indian Council of Medical Research (ICMR), which is the bare minimum ration. According to the author, the landless labourers and peasants operating upto one hectare of land, who constitute 47 per cent of the rural agricultural population, experience hunger and malnutrition in the most acute form. In several villages where land is infertile and in highly drought-prone areas, peasants operating more than one hectare of land also suffer from acute hunger and malnutrition. The single most important cause of hunger and malnutrition is inequality which deprives a majority of the population of access to resources which can be employed to produce food or yield an income for purchasing food.

Is India self-reliant in food? Self-reliance in food is defined as the ability to produce adequate quantities of all the food items which are part of the diet of our people and are an important source of nutrition for them. The ICMR has worked out the per capita requirements of basic foods for different age groups doing different types of work. This is multiplied by the total number of people in these age groups doing different types of work and summed up to get the requirements of basic foods at the national level in India.

Domestic production falls short of requirements in cereals, pulses, milk and oils and fats. Large quantities of edible oils and dairy products are imported. Besides large quantities of inputs used in the production of food like fertilisers and pesticides are imported. Thus india is not self-reliant in food which is contrary to what is being claimed in official quarters.

On the other hand, agribusiness promotes a massive wastage of food. In its ruthless search for profits, it ignores and hinders the basic task of making nutritious food available to a majority of the people. For instance, the loss of nutritious ingredients in the course of milling of rice and hydrogenation of edible oils.

A few regions produce a surplus of foodgrains (e g, Punjab and Haryana) while others remain deficient (e g, Bihar, Madhya Pradesh, Orissa and West Bengal). Similarly some crops have performed reasonably well (e g, wheat) while production of some others have relatively stagnated (millets and pulses). The per capita availability of millets (jowar, bajra, ragi etc), the food of the poor, has been declining. The production of pulses (chana, urd, mung, kulthi, masur etc), the poor persons protein, has stagnated. The biggest failure of the green revolution is the failure of high yielding varieties (HYVs) of rice. HYVs have failed to give the promised and much publisised higher yields despite the application of high amounts of fertiliser and irrigation water. The main reason for this failure is the high pest and disease susceptibility of the new HYVs relative to the resistance to disease and pests of the older varieties.

There is an interesting chapter on the long term adverse environmental effects of the green revolution development strategy in Punjab. The growth of legume crops (e g, grams) in rotation with cereal crops and inter-cropping practices used to be beneficial for maintaining the fertility of the land. However, during the green revolution period, the area under pulses went down from 13.4 per cent of the total area under crops in 1966-67 to 3 per cent in 1982-83 and the area under oil seeds has gone down from 6.2 per cent of the total area under crops in 1966-67 to 2.6 per cent in 1982-83. There has been a greater reliance on chemical fertilisers for maintaining the fertility of the soil relative to the use of crop-rotations, inter-cropping practices and dung. This tendency to rely more on chemical fertilisers for maintaining the fertility of the soil relative to other better and cheaper methods has been criticised by ecologists and other specialists. Thus Francis Moor Lappe and Joseph Collins write in their classic, *Food First* that "The more one relies on chemical fertilisers instead of manure, compost, crop rotation and green manure, the more the organic matter declines, the less able plants are to absorb inorganic nitrogen in chemical fertilisers. This helps to ex-

plain why US agriculture, according to biologist Barry Commoner, now uses about five times as much fertilisers it did in 1947 to produce the same amount of crop". In fact, the Punjab State Planning Board in a perspective plan for agriculture (1980-2000) notes that the heavy reliance on wheat-rice rotation has "upset the ecological balance of the state and the agro-ecosystem has become fragile".

In a country where purchasing power is concentrated in the hands of a small proportion of the population while the masses lack purchasing power, the rich spend extravagently on expensive food while the poor cannot even purchase essential foodgrains. The consumption of barley, used by the poor either as flour for making 'chapatis' or as parched grains to make 'sattu', has been declining. Instead barley is being diverted into the preparation of malt for producing beer, whisky, candy etc. The organisation of the milk trade has changed significantly in many areas. In earlier days when marketing of milk was not so extensive, a lot of milk used to be converted to ghee at the village level. A nutritious by-product called 'chaach' obtained in the process was consumed by the poor. Now, with extensive marketing facilities for fresh milk, lesser ghee is produced within the village and consequently the poor are deprived of 'chaach'. Thus, the poor are deprived of a significant share of milk-related proteins while chocolates and ice-creams are produced for the metropolitan market.

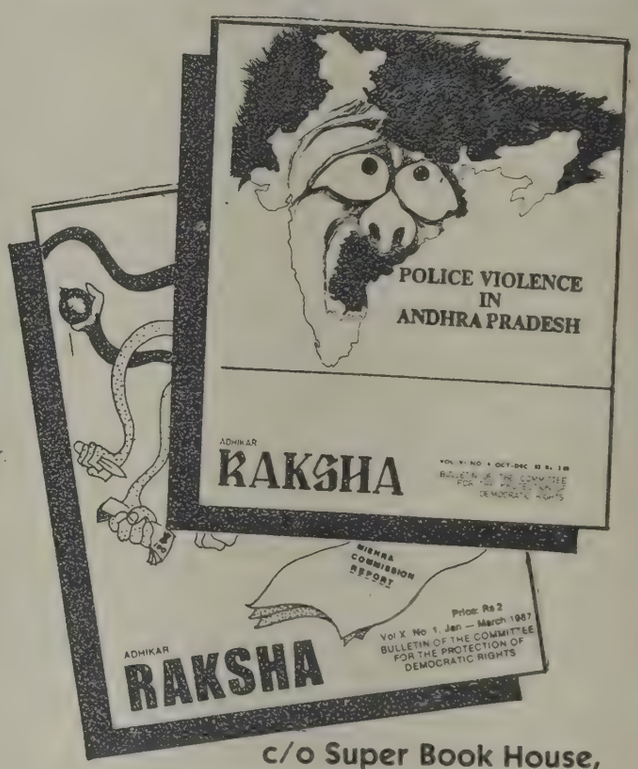
The export of rice, is clearly an undesirable trend. The existence of a 'surplus' stock is no reason for exporting especially when millions of hungry and malnourished people are deprived of adequate amounts of this staple food. Instead largescale employment generating programmes like soil and water conservation and afforestation could be launched.

India is the fourth largest exporter of tobacco. Tobacco not only takes up land that can be used to grow food crops but it also destroys the fertility of the soil. Export of fish and fish preparations has increased from 33,000 tonnes in 1970-71 to 90,000 tonnes in 1984-85. Capital and technology has been imported for deep sea fishing to step up exports, bypassing the protein needs of the poor local people.

The author outlines the elements of a solution, towards satisfying the nutrition needs of the people which include the implementation of radical land re-distribution special attention to forest conservation, and a revaluation of traditional farming practices. These measures will face formidable opposition from the ruling classes. Thus they can succeed only as part of a wider struggle for social, economic and political emancipation of the oppressed.

The book is a competent, radical overview of the food system in India. The author however focusses on the problems of hunger and malnutrition in rural India, but the urban situation has not been dealt with adequately.

Are you looking for news and analyses which rarely make it to the national press?
Reports about people largely ignored?



If you are, read Adhikar RAKSHA — the voice of the civil rights movement, the only real Opposition today

Started in 1977 after the Emergency, brought out from Bombay every quarter, it carries reports by civil rights groups all over India: be it excerpts from the banned **Oppression in Punjab** by VM Tarkunde, or from the Mishra Commission Report; historical judgements or protest poetry

To discover
the true nature of the Indian State
the myriad violations of our rights

THE new drug policy was announced on December 18, 1986. The total thrust of the drug policy is antipeople—the prices of various drugs will increase substantially (50 per cent to 300 per cent). Also, the new drug policy has given undue concessions to foreign multinational drug companies and monopoly houses of India. The small and medium manufacturers along with public sector will get a set back with this new drug policy. Its above impact can be understood with one example.

Earlier all the vaccines were being manufactured by the public sector in India. There may be multi-factorial reasons for these vaccines being in short supply, but in whatever limited quantity, these were being provided to the general public free of cost in government hospitals.

One example can be taken that of antirabic vaccine. There have been many reports in newspapers about the short supply of these vaccines in governmental hospitals. The reasons of less production and lacunae in regular supply have not been thoroughly evaluated. The new drug policy has given the option to private companies to manufacture these vaccines.

One of the companies Behring Biologicals, a division of Hoechst India Limited has come out with an antirabic vaccine with a brand name of 'Rabipur'.

The various advantage of this vaccine over the already produced vaccine by public sector are documented as follow:

— New generation tissue culture vaccine.
— Potent.
— Safe.
— Economical.
— It is to be given intramuscular instead of intraperitoneal. The dosage is one injection on each of days 0, 3, 7, 14, 30 and 90 (hence less drop out).
— Rabipur should be stored protected from light at +2 to 8°C.
— Cost of 1 ml. is Rs. 100 whereas total dose is 6 ml. Thereby cost is Rs. 600 for one patient.

New certain questions can be raised.

How is it economical?

a) Its cost is Rs. 600 for one course whereas the cost of vaccines manufactured by public sector is Rs. 40 per vial, whereas this was given free of cost in the government hospitals.

b) Moreover immunoglobulins are also recommended along with Rabipur injections which entail further cost of Rs. 300-400.

c) Even a lay person can understand how far economical it is! Of course it can be said to be economical when the cost is, compared with other brand names where cost is Rs. 2100 for one course.

Is it potent and safe?

The advertisement pamphlet reads as under:

1. Slight reactions at the site of injection such as pain, erythema and swelling may occur in less than 5 per cent patients.
2. Isolated instances of lymphadenopathy, headache, lethargy, slight elevations of temperature and allergic reactions of skin have be reported.
3. No experiences are yet available with regard to administration during pregnancy.
4. This should not be used where there is a known allergy to neomycin, chlortetracycline, amphotericin B, or chicken protein. Prophylactic vaccination should not be undertaken.

The above statements made by the company themselves raise many suspicions.

1. Is the vaccine really as safe as claimed?
2. Will this be experimented on pregnant woman in India as many other drugs are being experimented. Does the company consider that Indian pregnant women are guinea pigs?
3. The only thing which is an improvement is that the route of administration is intramuscular rather than intraperitoneal but as the number of abscess formation in S/C or I/M immunisation is increasing who knows what will be the percentage of abscesses with this I/M injections.

The new drug policy by opening vaccine manufacture to private firms will only cater to the needs of those who can pay Rs. 600 to Rs. 2000 for simple antirabic vaccination.

Myth of Alternative Medicine

thomas george

THE so-called 'radical perspective' of medicine has many degrees, but all of them agree that modern medicine is more or less bad, ineffective and expensive while traditional medical systems are projected as a sort of magical remedy to all health problems. This view has gone into the folklore of self-proclaimed 'radical' writers and has been repeated ad nauseam, without discrimination of scientific examination. A close look at this concept reveals several fundamental flaws; to the extent of making it a reactionary rather than a radical view point.

In the first place, the glorification of traditional systems is utopean and unrealistic. To keep recalling bygone 'golden ages' is fruitless. The fact is that at the present time, all traditional

systems of medicine are primitive and ineffective in comparison to modern medicine. To call for research in these systems is one thing, to project them as qell-developed, near-perfect systems is quite another. In fact, the whole business of counterposing modern medicine and traditional systems, of making them appear antagonistic and mutually exclusive has no basis in reason. Any scientific system will incorporate the results of research and any boundaries are artificial and foreign to scientists. These boundaries definitely do not serve the cause of science and are of use only to vested interests who make a living out of such divisions. When one comes down to the nitty-girtty and asks for a point-by-point delineation of the ways in which traditional medicine is superior, one comes up, not against a wall, but against a mass of fluff—vague statements about being closer to the people, arising out of their milieu etc. When one is sick, it may be reassuring to see one's grandmother but far more effective to see one's doctor! All this boils down to saying that promising lines of enquiry in any system should be subjected to rigorous scientific research and the results integrated into the knowledge available in health care. To rigorously demarcate 'systems' is ridiculous, wasteful and unnecessary.

On the question of cost also, one finds that the idea that ayurveda, siddha or unani is cheap, an idea that the 'radicals' have been trying to ram into our minds, is far from true. These systems as they now exist are expensive, often more so, than modern medicine. In this context it is surprising how self-proclaimed socialists make such a fetish about cost. The ultimate aim of a socialist system is to provide the best life for its citizens, not the cheapest. In fact it is interesting that emphasis on traditional systems finds so much favour with foreign aid agencies, many of them wings of multinational companies, doing business by other forms. One possible reason for this favour is that giving respectability to all the quacks in the countryside is a cheap way of preventing rural people from demanding better health care. To provide really good medical care of the quality available in the west would be expensive. How much easier to give the shadow—and go on a propaganda campaign to pass it off as better than the substance! And it is this very ludicrous propaganda that the 'radicals' have swallowed. They have now put themselves in the silly position of saying that the best is too good for the poor, that they should have only what they are accustomed to—quacks and magic remedies!

The talk of community health and the attempt to produce non-existent antagonism between preventive and curative services, is all part of the attempt to cloud the real issues by posing symptoms of the disease as the disease itself. To cover up the lacunae in the health services and the wocfully inadeqauate budget spent on it by the expedient of posing it all as a problem of priorities is nothing short of criminal. And when 'radicals' accept this kind of solution, they in effect accept that the health budget is adequate, its all a matter of more judicious spending, they accept that the best care is impossible; attitudes that are not only defeatist, but a grotesque travesty of the truth.

The true radical viewpoint on health would be that the most scientific and effective system should be available to all irrespective of cost. One can accept compromises in the interim period towards achieving the goal, but any attempt to pass off the compromises as better than the goal itself should be stoutly resisted. We cannot accept second class care as good enough, for the poor. It is the duty of every democracy to provide the best in all fields for all its citizens and this is the objective for which we should fight.

ADVERSE EFFECTS

Women and the Pharmaceutical Industry

Edited by Kathleen McDonnell

Medical remedies which are inappropriate, wasteful and sometimes simply downright dangerous, overload the world. Many are targetted specifically at women. ADVERSE EFFECTS sets out to examine, in a global context, how women are frequently exploited and injured by drugs. Articles from India, the Philippines, Canada, the Netherlands and USA illustrate how women are successfully organising themselves to fight this ill-treatment and manipulation.

'ADVERSE EFFECTS is essential reading for health activists everywhere.'

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or Marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (for issues). I am sending Rs._____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

PHYSICIAN'S OATH
AND
STATEMENT OF MEDICAL ETHICS

(Adapted for the nuclear age)

Over the millenia
physicians have evolved a long tradition of ethical affirmation,
represented originally by the Oath of Hippocrates, and later
by many other national and international codes and
statements of professional ethical obligations.

Recently in May 1983

the World Health Organisation General Assembly stated that,
'nuclear weapons constitute the greatest immediate threat
to the health and welfare of mankind', and that physicians
'have both the right and the duty to draw attention
in the strongest possible terms to the catastrophic results
that would follow from any use of nuclear weapons.'

To our long tradition of ethical statements
we believe that there should now be added:
"As a physician of the 20th century, I recognise
that nuclear weapons have presented my profession
with a challenge of unprecedented proportions,
and that a nuclear war would be
the final epidemic for humaking.
I will do all in my power
for work for the prevention of nuclear war."

Proposed at the Third Congress of International Physicians for the Prevention of Nuclear War. The Hague. June 17-21. 1983

Vol. II June-September 1987 Nos 1-2

Technology in Medicine

SOMETHING is tearing apart the noble mask of medical practice. A gigantic force is shaking its traditional independent status. Some say that machines are the culprits—they have made medicine invasive, costly and impersonal. Some are concerned about new the organisational set-up—bureaucracy is the devil, large size is wasteful, so 'small is beautiful'. Undoubtedly, the introduction of new machines in medical care has not only made medical technology visible, but also made it an independent issue for discussion and for evolving alternative practices. They have also widened the scope of discussion by naturally making it open to people other than doctors. Ironically, while monopoly capital has introduced them into medical care, they have made a dent in the monopoly of doctors to discuss medicine.

Medical technology, to use a broad definition includes drugs, devices and medical and surgical procedures used in medical care, and organisational and support system within which such care is provided. This definition is applicable to all systems of medicine. We, however, restrict ourselves to allopathy. For allopathy is the dominant medical system internationally, it has an organic link with capitalism—the dominant socio-economic system—and above all, we have insufficient information to correctly understand the role and nature of technology and emerging trends of technological change in the context of capitalist development in other systems of medicine.

While discussing new and recently-developed medical technology—for that matter all such technologies—we need to recognise that most of them are not developed by the application of advances in the basic sciences in one field. New medical technologies are not only founded on the developments in the basic sciences in medicine alone, but also on the combination of this with developments technologies in other fields. For example, the cardiac pacemaker was developed by using advances made in solid state physics, developments in vaccum technology, electrical engineering as well as in anatomy and cardiac physiology, and surgical techniques and development of silicon rubber and epoxy resins.

Though on the face of it a technology seems to develop out of the accumulation of scientific and technological knowledge and skill, this accumulation is encouraged, discouraged and selectively manipulated in the socio-economic context. Further, the diffusion for widespread use of any technology is determined by these forces. In the case of medicine, the flow of capital into the medical service sector and the concommitant organisational maturity of medical care system provided an objective basis for widespread diffusion of new medical technology in the advanced capitalist countries.

Penetration of Capital into Medical Services

Medical care is predominantly organised as (1) individual and group medical practice which has its roots in the petty commodity production in which the physician owned his/her skills as well as essential tools, (2) organised hospital-based medical care which has traditionally been charitable, state-financed or owned, or non-profit voluntary. Historically, though health care particularly, its public health component was recognised as an essential economic function as early as the mid-nineteenth century, the penetration of private capital and consequent capitalist industrialisation of technological components of medical care took place much later. This was due to the specific place of the service sector in the capitalist economy. Services of all kinds, including medical service, rendered as a commodity or otherwise, are essential to capital to revitalise, reproduce and even improve labour power. But they do not in the process of actual rendering of services, produce surplus value. Capital on the other hand, flows naturally into the surplus-value producing sectors of economy.

Therefore, the initial penetration of capital into the medical service began into those technological components of medical care—notably the tools of the physician—which could be converted into commodities containing surplus value. Thus, the physician who was a petty commodity producer gathering herbs, chemical, etc, and compounding them into medicine to dispense it to the patient, was gradually alienated from these tools. The doctor became dependent on the supply of that tool (medicine) from capital. The doctorl no longer remained an independent petty commodity producer, although he/she did retain the character of the individual private medical practitioner. The latter characteristic was not radically affected because the doctor retained the exclusive knowledge and skill of prescribing drugs produced by the industry. The doctor still remains indispensible for sale of (and realisation of the use value of) the commodity drug. Therefore, doctors are the most important target in capital's market strategy. For this purpoe it is necessary that the doctors identify with the interest of capital. The common method used for such purpose by the industry is ideological, combined with material incentives. In the situation of intense competition, the industry consciously promotes irrational use of drugs and the use of useless drugs. This interest of the industry is well-reflected in the doctors irrational prescription practices. Indeed, once the doctor became the last executor of capital's market strategy, irrationalism was bound to dominate medical practice.

The rise of monopoly capitalism and the changes in its dynamic during and after the second world has provided objective basis for further technological changes in medical practice. In late monopoly capitalism there is a continuing compulsion to increase the rate of surplus value, to valorise the excess capital by investment in any possible area (such as armament, services, etc) and to lower cost of production through mechanisation and automation. In this situation, one of the best ways to preserve monopoly market is to accelerate technological innovation and consequent rapid introduction of new products in the market. This creates a situation of permanent technological and product renewal. This also creates a permanent need to dispose of obsolete technology and the product to the less developed countries (hence the slogan of technological transfer, albeit in neo-

colonial ways). It is this characteristic that is primarily at the root of continuous introduction of new drugs, devices and hosts of other things, irrespective of actual medical needs and priorities of the people, into medical practice.

Mirror effects of these developments are also seen in a third world country like India, due to neocolonialism as well as due to the needs of indigenous capital. The economic backwardness of the country puts certain limits on the extent to which capital can penetrate medical services sector and new medical technologies can be brought to widespread use. However, these limits are not absolute. Nevertheless, the forceful entry of new medical technologies has created forces which are transforming individual medical practice as well as hospital care much more extensively than the proportionate economic value of such technologies.

Recent Technological Changes

Since the late 1960s after making its initial impact on the production of drugs, the logic of late monopoly capitalism started affecting other medical technologies. Within a decade it unleashed a massive assault on medical care with a plethora of new diagnostic and treatment devices. Not only have new technologies entirely taken over the essential functions of doctor in a medical care but aids him/her in performing those functions. (They also create new functions.) In the process each function becomes a specialised one as it needs the aid of a special, complicated and costly machine. Thus a rapid division of diagnostic and treatment functions takes place. These changes in medical care also accelerated certain changes in the way medical care is traditionally organised.

In the sector of individual private medical practice many new private practitioners with technological spaciality were added. Indeed we have come a long way from X-ray clinics to CT scan centres. The proliferation of diagnostic centres run by individuals, institutions or companies has lengthened the route which the patient travels in order to get diagnosed and treated.

The accelerated fragmentation of functions has further impersonalised medical care. The business nexus of generalists, specialists (medical), specialists (equipment), diagnosticians and what not have expanded the naked play of market forces (with the attendent corruption and irrational medical practices) in medical care. No wonder all these escalate the cost of medical care.

In hospital-based medical care too far-reaching changes have unfolded. Fragmentation has increased the number of departments. New equipment and procedures have led to a new division of labour inside the hospital. The need to coordinate all such activities has given rise to such bureaucratisation that even many old styled but business-oriented doctors have started feeling uncomfortable. The costly requirements like controlled environment for equipment, posh premises to match the high cost of services, etc, make hospitals a huge investment. Thus the gradual conversion of traditional non-profit and charitable hospitals to for-profit and fee-for services hospitals is inevitable, though this is at different stages and in countries where state services are there, it is generating powerful forces for privatisation.

These changes are also accompanied by another significant development. Capital for the first time showed interest in going beyond the production of drugs and devices to organising hospital based medical care in line with industry on a large scale. Investor owned or corporate hospitals have concerned significant proportion of hospitals in developed capitalist countries while in India the process has barely started with the Apollo hospital in Madras.

With this, discussion on proletarianisation of doctors is no longer academic. Doctors seeking employment is not new. What is new is the logic of corporate for-profit hospitals, absolute control by the capitalists, continuous introduction of new technologies, inevitable need to use them at high price to realise investment and earn profit etc. That is profit is no longer incidental or one of the parts of a doctor's medical practice. Medical practice is now incidental to the organisation primarily devoted to profit.

Social and Ethical Issues

The production and sale of irrational and useless drugs with doctor's prescription over-the-counter and even selling prescription drugs directly by the chemists are well-known to us. We do not elaborate on it here as it forms a separate subject for discussion. However, it should be noted that by the time new equipment based medical technology made its entry, the doctors had sufficiently encouraged the technology culture (capsule and injection) amongst people or section of people that matter for it to build further upon.

Since the new technologies are very expensive and in short supply, it has to be rationed. In the market economy, this rationing does not take place according to need but according to the capacity to pay. This is not a new ethical issue. But earlier it did not confront the doctors so blatantly as it does today with new technologies.

The doctor is also confronted with legal problems, more of them where medical insurance has taken roots. Witholding a diagnostic procedure or delaying treatment with certain equipment invite a spate of litigations in many advanced capitalist countries. Doctors pay huge sums as premium to insurance companies to protect themselves from bankruptcy. In the US they have now even agreed to allow their colleagues to review or assess their competence. This has accelerated the production of literature on medical ethics to equip them with enough knowledge of law and pitfalls in practice. In our country this aspect is yet to become major issue.

Despite the high cost and legal issues, the fast use of such technologies is an absolute need for capital. To generate quick demand from the people, more elaborate methods are used than just enlisting doctors, support. So it goes beyond the doctor, directly informing people. This is one of the reasons why in our country import of a nuclear magnetic imaging makes front page news. In this way unnecessary use of such equipment is systematically organised.

As said earlier, technological obsolescence being a major problem, the traditional methods of assessing technology before its introduction are waived. Most of these new technologies are accepted on the basis of description of their excellence, but not tested through careful trials. Neither com-

(Continued on page 35)

Development of Medical Technology

The Example of Neurology

bindu t desai

The brain has remained an enigma through millenia despite the fact that the vast progress in medical technology has helped to visualies it and for its functions to be studied directly and indirectly. This article traces the impact of medical technology on our current understanding of the brain and its role in the developments in neurology. It points out that while some innovations in different branches such as physics, electronics, etc definitely aided the physicians' understanding, often tools which have evolved have ended up being overused. Moreover, even its necessary use has come to be confined to the class which can afford to pay the fancy prices that are charged. Medical technology is thus neither value neutral in its evolution nor in its use.

THE explosion of medical technology in the last century, especially the past 25 years has irreversibly changed the face of medical practice all over the world. This phenomena, greatly accelerated by the advent of the transistor and miniaturised electrical gadgets was rooted in the Cartesian school with the question of mind and soul separated from the body, dealing with the latter as a machine to be understood and treated as a sum of its parts. If its philosophical origins are found in Descartes its ability to discover, probe, explore, remove, and sometimes cure illness is almost wholly due to the enormous advances in human understanding and knowledge about the nature of the electromagnetic spectrum.

Medical technology is no more value neutral than any other technology. It arose in the dynamic expanding world of an aggressive, confident European mercantilism. Today it is still only available at a price and with priorities set by the successors of those merchants. It has benefited from the European Renaissance, the scientific revolutions of the 17th and 18th centuries and the atomic age. This article will review at some length the history of the development of medical technology emphasising its philosophical origins. It will comment on the impact of modern medical technology on diagnosis and treatment, and discuss the advantages as well as problems accruing from its ascendency. I shall use the example of neurology for two reasons; first being a neurologist I felt competent to comment critically on the development and impact of technology on neurologic practice; secondly, the nervous system has presented medical technology with its geatest challenge as this organ system has been virtually inacessible to human manipulation until a few decades ago. Also the correlation between structure and function of the brain is rudimentary compared to other organs like the heart, liver or kidney.

While a review of development of technology in many important aspects of the neurosciences has been attempted some topics like neurophysiology and neuroradiology have been covered extensively, others like neurosurgery rather cursorily. This uneveness, partly due to personal interest in the early history of the discovery and investigation of electricity and its role in neurology, reflects the difficulty of reviewing such a vast topic except at inordinate length.

Development of Neuroscience

The function of the brain, its effect on consciousness and limb movements must have been evident to hunters even in the Paleolithic age. The first recorded description of the brain and its coverings are found in Egyptian papyri written around 500 BC (McHenry 1969, p e). In ancient Greece, Pythagoras (582 BC-500 BC) taught that the brain was concerned with reasoning. His discovery of mathematical principles underlying music and the three sides of a right angled triangle for which he is renowned represent the first examples of the human mind's ability to give theoretical concepts a reality of their own (Bergland, 1986, p 10). A student of Pythagoras, Alcmaeon performed one of the earliest recorded dissections of the human body (sixth century BC) and described the optic nerves. Further progress about knowledge of brain structure and function took a tortuous course. Some of the prominent authorities on brain function like Aristotle (384-322 BC) and later Galen (130-200 AD) seem not to have dissected a human brain (Spillane, 1981). Their ideas of the brain as a cooling organ (Aristotle) or as the transformer of the quintessence of life or pneuma into an animal spirit which in turn was carried through the tubular nerves to the body (Galen) may have arisen because of their ignorance of its structure. Dissecting the human body was frowned on at various points in history in Greece (Spillane, 1981, p 7), in India (Basham 1967), and later by the Catholic Church (Bergland, 1986 p 54). However many observers were aware that the brain was the seat of intelligence, dreams and thought. Hippocrates of Cos (400-370 BC) wrote:

> Men ought to know that from the brain, and from the brain only, arise our pleasures, joys, laughter and jests, as well as sorrows, pains, griefs, and tears. Through it... we... think, see, hear, and distinguish the ugly from the beautiful, the bad from the good, the pleasant from the unpleasant. (Bergland, 1986, p 28).

Erasistratus of Chios (circa 310 to 250 BC) was struck by the greater number of convolutions in the human brain compared to animals. He related this difference of the superior intelligence of humans. But for nearly two centuries the heart was considered the organ of rational thought in Europe and curiously also in India (Basham 1967; Winter 1975). In Europe, Aristotle's views reigned supreme: pneuma from heaven came to the heart via the trachea and lungs. The brain was a cooling gland that regulated the temperature of the pneuma brought to it by the arteries.

In addition to mistaken ideas about brain function, knowledge of brain structure was limited by the peculiar biologic properties of the organ. The brain is extremely soft and friable with its components easily distorted or destroyed unless the organ is frozen or hardened by the addition of a fixative like alcohol or formalin. (EScourolle and Poirier, 1973). Only in the eighteenth century was the technique of fixation of brain tissue by alcohol developed which allowed

adequate dissection of brain tissue (Spillane, 1981, p 18). Thus neuroanatomy illustrates a feature common to all aspects of neuroscience and even science in general: the observation of Thomas Kuhn regarding the dependency of creative thought on technological advancs (Kuhn, 1962). Prior to the fixation of the brain by additives one can only speculate on the reactions of observers to brain tissue "oozing like porridge from the skull in a battlefield or even when delivered promptly with the severed head from an executioner". Covered by membranes, full of convolutions and cavities it must have appeared " a most mysterious object of exploration" (Spillane, 1981, p 18).

Along with countless other branches of knowledge, medical science grew by leaps and bounds with the coming of the Renaissance (1440-1540 AD). Printing allowed technical advances to be disseimated rapidly and effectively. Andreas Vesalius' (1515-1564), *De Humani Corporis Fabrica (The Fabric of the Body)*— the most complete and accurate description of the human body was published in the same year (1543 AD) as Nicolas Copernicus' *De Revolutionibus Orbium Coelestium (on the Revolution of the Celestial Orbs).* Earlier Leonardo da Vinci (1452-1519 AD) had drawn an outline of the ventricles of the brain. He had first inserted a needle in the ventricles, filled them with melted wax and used the casting techniques of bronze sculptors to delineate the shape of the cavities of the brain. Vesalius' anatomical studies led him to question Galenic physiology though he refrained from criticising Galen. Later, in 1629, William Harvey, a student of the School of Medicine at Padua founded by Vesalius, discovered the pump-like function of the heart, described the circulation of blood and helped overthrow Galenic concepts of the pneuma and other mysterious spirits. In the opening year of the seventeenth century Giordano Bruno (1548-1600) was burnt to death for his vision of an infinite universe. When the century ended science had come of age, Galileo (1564-1642) had displaced the earth to its modest position in the solar system, Aristole had been dethroned, his dynamics discarded.

The phenomena of magnetism was described at length by William Gilbert (1544-1603) in *De Magnete* published in 1600. Gilbert was a court physician to Elizabeth I. Magnets, he showed, possessed the virtue of attraction. Force could be exerted by material bodies which were not in contact with one another. Gilbert exemplified the experimenter scientist who Francies Bacon (1561-1626) deemed necessary for the advancement of learning. Speculation was to be replaced by observation, vitalism by mechanisms. Magic lost its hold as an explanation for natural phenomena in the seventeenth century as science unravelled some of these mysteries. It was the era of mercantile capitalism, of the formation of the Bank of Amsterdam in 1609, the Bank of England 85 years later, of the Dutch and British East India Company, of the horrific Middle Passage which for over three centuries carried some 13 million African slaves to the New World. With the development of trade over long sea routes to the Americas, India, China and Indonesia came the imperatives of more accurate navigation charts, skilled shipbuilding, of better implements of war, of a union between merchant and scientist, of education no longer under the aegis of the church but of new colleges which quickly became centres of science. Gresham College, in London, founded in 1579 with monies provided by the will of Thomas Gresham, a financial agent to the Crown and founder of the Royal Exchange, was where the Royal Society first met (Bernal, 1971, p 459). The scientific revolution had begun, everywhere old dogmas crumbled. Descartes' (1596-1650) *Discourse on Method* (1637) discussed a new system which "exhibited that individual arrogance which was one of the great liberating features of the Renaissance, the same arrogance that expressed itself in the great navigators, in the conquistadores, in all the defiances of authority that characterised the end of the feudal period and the beginning of one of individual enterprise" (Bernal, 1971, p 443). "I think therefore I am"—mind became more certain than matter, Aristotle's three souls were dispensed with, only one, the rational soul existed and that too only in the human. It resided in the pineal gland. Descartes' philosophy completed the dualism of mind and matter. Later Cartesians dropped the emphasis on the pineal gland and sought to explain living organisms by the laws of physics. "If all movement of matter were determined by physical laws, mental events must be equally determinate" (Russell, 1945). Even the soul was composed of atoms, thought came from the movement of atoms. Descartes also commented on the conditioned responses that would be described by Ivan Pavlov (1849-1946) over 200 years later. "If you whip a dog five or six times to the sound of a violin he would begin to howl and run away as soon as he heard that music again" (Brazier, 1984, p 24). Descartes recognised the need to explain how the contraction of one muscle must be accompanied by the relaxation of its opponent. His legacy was the mechanically operating model of the human body, a model very influential in medical science even today.

Antoni van Leeuwenhoek (1632-1732 AD) opened the world of small things with his microscope just as Galileo had uncovered some secrets of the stars with the telescope. His study on nerves, hampered by lack of hardening or staining techniques, left him a convinced Galenist—nerves were little canals which carry humor. So the first use of the microscope did not clarify nerve structure. Indeed the issue remained unresolved even a century later (Brazier, 1984, p 37).

Arguments continued about the release of spirits down the nerves, spirits that led to muscle contraction. Outstanding physicians like William Croone (1633-1684) and Thomas Willis (1621-1675) did not "confront the problem defined by Nicolaus Steno (1635-1686); The (muscular) heart continued to beat when taken out of the body, cut off from its nerves and blood supply (and from the soul)" (Brazier, 1984, p 62). Giovanni Borelli (1608-1679) found that when an animal was submerged in water, and its muscles were slit open no bubbles appeared in spite of vigorous muscle contraction by the struggling animal. Therefore he felt, muscle contraction could not be due to gaseous spirits. As the Seventeenth Century drew to a close science had become organised in the manner suggested by Bacon. Powerful scientific societies replaced groups meeting in private homes, scientific journals were started and publishing houses were established that brought out only science related books.

The eighteenth century established science as an indispen-

sable feature of what was to become the Industrial Revolution. Capitalism was transformed from a "phase dominated by merchants and small manufacturers to one dominated by financiers and heavy industry" (Bernal, 1971, p 503). The age of European colonisation was about to begin. The history of America, Africa and Asia would now reflect indelibly the consequences of those ships that had come to their shores over 200 years ago. For Europe would discover from this century onwards the principles governing essential properties of matter like electro-magnetism, it would harness the power of steam and achieve its dominance of other continents aided by the knowledge of these powerful forces in nature. In addition, the seventeenth century had seen the first revolution in Europe; the Civil War and the execution of Charles I of England. These were only the most dramatic manifestations of a world in ferment. In the ideas of the Levellers and the Diggers the seed of a society equal and free from exploitation was eloquently expressed by Gerard Winstanley:

> Freedom is the man that will turn the world upside down, therefore no wonder he hath enemies. . . the earth should be made a common treasury of livelihood to whole mankind, without respect of persons" (Hill, 1975).

These revolutions would recur in America and France in the eighteenth century, the questions raised and problems faced by them continue to confront us today, from general societal issues to the availability, relevance and effectiveness of modern medical technology.

The intellectual advances of the eighteenth century made that period famous as the Age of Enlighenment. Theories about brain function changed and the nervous system could be explained without the existence of a soul. D'Alembert (11717-1783) one of the co-editors of the Encyclopedia shared John Locke's (1632-1704) view of the nervous system; all knowledge was derived from sense experience, hence the sciences should be based on actual perception. The relationship of the brain to the spinal cord was still a puzzle. The function of the nerve roots that were attached to the cords was unkown. Jacques-Benigne Winslow (1669-1760) introduced the concept of a 'sympathetic' system made of 'small brains' or ganglia that were centers for communication between the nerves and various organs. Jiri Prochaska (1749 1820) proposed a purpose for unconsciously initiated movements—preservation of the individual. Such a purpose made the teleological significance previously ascribed to these movements irrelevant.

Discovering Electricity

Many experiments began investigating the new and mysterious phenomena of electricity. Perhaps it was related to nerve conduction. By the early 18th century it was already known that the human body could be charged electrically if it was insulated from the ground. At first it was thought that a layer of air had to be present between the subject and the ground. The characteristics of conductors and non-conductors were only beginning to be understood (Brazier, 1984, p 176). More knowledge about the nature of electricity was necessary before its action on an animal's body could be studied. Also if animal tissue itself produced electricity, the current produced would be very small and need exquisitely sensitive instruments to detect it. These gadgets designed crudely at first by Alessandro Volta (1745-1827) would be modified later by Waller (1887) and Einthoven (1903), (Cooper, 1986), Adrian (1929) and Berger (1929), (Licht, 1971) to herald the use of electrocardiography, (EKG), electromyography (EMG) and electroencephalography (EEG) respectively.

These developments came slowly. Initially a technique for sorting an electric charge had to be discovered. It happened accidentally to Petrus van Musschenbroek (1962-1761) at the University of Leyden. Musschenbroek had been trying to conserve electricity in a conductor and delay the loss of its charge to the air. He thought electricity was a fluid and tried at first to fill an empty glass jar, then one filled with water with this fascinating effluvium. He charged the water with electricity with a wire leading from an electrostatic machine, but to no avail. The electricity dissipated once the electrostatic machine stopped running. One day, his assistant, Andreas Cuneas picked up the jar containing charged water in one hand and at the same time reached out to remove the wire from the electric machine with the other hand. On touching the wire he got an electric shock—his hand had formed one 'plate', the charged water another, and the glass jar the intervening dielectric. A condenser was born (Brazier, 1984, p 180). The Leyden jar as it was called later contained no water, instead it was coated on its inner and outer surface by a tin foil. The jar became a source of entertainment. The Abbe Nollet (1700-1770) used it for a spectacular demonstration of electrical power. He lined up a human chain of 180 soldiers at Versailles for the benefit of the King of France. The entire line of soldiers leapt into the air when the men at each end touched the poles of a Leyden jar. The Abbe repeated this experiment for the Monks of Chartreuse this time using a human chain 3 kilometers long! (Skilling, 1948). The Leyden jar was used by all kinds of 'medical' men to treat a variety of nervous ailments. John Wesley, the Methodist-reformer who wrote a pamphlet on the subject said that he was "firmly persuaded there is no remedy in nature for nervous disorders of every kind, comparable to the proper and consistent use of the electrical machine" (Schiller, 1982, p 4). Electrotherapy persists today in many forms as ECT or electroconvulsive therapy for some psychotic disorders, as trancutaneous and spinal cord stimulation for relief of pain and for relaxing spastic muscle and the EEG is used in biofeedback therapy. The scientific basis of these therapies are unclear, their usage sometimes as in the case of ECT, being based on the erroneous observation that since epilepsy and schizophrenia never occurred in the same patient, convulsions might result in elimination of the symptoms of that psychosis (Solomon and Patch, 1974).

Meanwhile, in the eighteenth century research began on the torpedo fish whose power to shock was known to fishermen and whose ability to cause pain was thought by Ibn Rushid (Averroes) (1126-1198) to be similar to the effect of a lodestone. In 1972 Abbe Lazzaro Spallanzani studied the anatomy of the torpedo in terms of its ability to shock. He was convinced the shock was electrical, a fact which Luigi Galvani (1737-1798) later confirmed. Galvani cut the nerve

supply to one side of the electric organ of the torpedo and found that this side failed to discharge. On svering the head of the fish the discharge was destroyed even though the heart was intact. The mechanism of electrical discharge thus was independent of the circulation. Electric fish aroused sustained scientific interest for here was an animal that produced electricity. But was animal electricity similar to the one physicists studied? Was it triggered by the brain? Michael Faraday (1791-1867) gave an ambivalent answer to the first question, he was not convinced that nervous fluid is only electricity. The second question remained unanswered for a century because there were no instruments to detect the passage of small currents.

Galvani's *Commentary on the Effects of Electricity on Muscular Motion* was published in 1791. Although Galvani was only one of several individuals like Caldini and Fontana who had directly stimulated nerves with electricity, and his discovery came about accidentally like the Leyden Jar, his commentary enabled the science of electricity and physiology to come together and 'each took a great leap forward' (Spillane, 1981, p 147). On 20th September 1786 Galvani had dissected out a nerve-muscle preparation of a frog and placed it on a table on which an electrically charged frictional machine lay at some distance. In Galvani's words "when by chance one of those who were assisting me gently touched the point of a scalpel" to the exposed nerves of the frog "immediately all the muscles of the limbs seemed to be so contracted that they appeared to have fallen into violent tonic convulsions. But another of the assistants, who was on hand when I did electrical experiments, seemed to observe that the same thing occurred whenever a spark was discharged from the conductor of the machine" (Spillane, 1981, p 146). An electrical charge had been transferred to the insulated nerve-muscle preparation by induction from the machine nearby. Galvani then studied 'atmospheric' electricity lightning in a thunderstrom to excite frog legs. The lightning conductor was invented by Benjamin Franklin in 1753. Interestingly Franklin's rebel tendencies had irritated George III who insisted that the lightning conductors at his palace should have round knobs instead of the sharp points Franklin had suggested! (Bernal, 1971, p 602). Galvani attached one end of a frog's leg to an iron wire antenna under the roof of his house and to the other end a wire that led to the water of a nearby well. When lightning flashed in the sky the frog muscles contracted. Later he found that frog muscles contracted when hung on iron gratings by bronze hooks that penetrated the spinal cord, irrespective of atmospheric conditions (O'Leary and Goldring, 1976). Though Galvani was aware that the muscle contraction arose because of contact between dissimilar metals he saw it as proof of animal electricity. In 1975 Volta showed that the frog leg merely served as an electroscope. Volta produced electricity without any animal at all, he simply put two plates of metal one of copper, the other zinc with liquid between them and invented the first electrical battery.

Galvani and Volta differed in their attitudes to Napolean who was then the first consul of France. Napolean conquered the area of Lombardy coverting it into the Cisalpine Republic with himself as its president. Galvani refused to take the oath of allegiance to the Republic and lost his position at the University of Bologna, while Volta supported Napolean and was honored with medals, and a title (Brazier, 1984, p 215; Skilling, 1948, p 44).

The French Revolution resulted in the formation of the Ecole de Medicine and the Ecole Polytechnique which became models for scientific teaching and research. Only the most eminent scientists were employed as salaried professors. The gentlemen amateur and the patronised client scientists of the past were thus replaced. In the Napoleanic period the first counsul turned emperor took a personal interest in science. He saw the utility of science for industry and war.

With the nineteenth century came revolutionary advances in the knowledge of electricity. In 1820 Oersted (1757-1851) accidentially found that electric current deflected a magnetic compass needle at a right angle to the current. Ampere (1775-1836), Gauss (1777-1855) and Ohm (1787-1854) studied the magnetic fields produced by currents. Faraday showed that a magnet moved near an electric conductor produced a current, a discovery of enormous practical significance because electricity could be produced by mechanical action and used to operate machines. The science of electromagnetism was born. It is striking that the Leyden Jar, Galvani's animal electricity and Oersted's observation of magnetic deflection were accidental discoveries. Thomas Kuhn has commented that the difficulty in science is not in making a discovery, but to know one has made it (Kuhn, 1962). This is particularly true when existing theory cannot explain or predict phenomena. The people who are likely to succeed are generally "sufficiently broadminded, and sufficiently critical or ignorant of orthodox theories to make the discovery" (Bernal, 1971, p 608). The belief that electricity is the 'stuff of thought' began with Benjamin Franklin who wondered whether it was the unseen force that extended through our universe. The study of brain electricity was pursued from Galvani onwards. It has helped to understand some aspects of brain function but has been sadly ineffective in solving the problems of brain disease (Bergland, 1986).

The first half of the nineteenth century saw an increase in knowledge about the internal structure of the brain. Johann Reil (1759-1818) studied the lobes of the cerebellum, and by soaking the brain in specific salt solutions was able to separate bundles of nerve fibers that carry specific messages from the body to the brain and vice versa. Luigi Roland (1773-1831) described the cerebral convulutions, Charles Bell (1774-1842) demonstrated that the anterior nerve roots of the spinal cord carried messages that led to movements of muscles, while Francois Magendie (1783-1855) showed that the posterior nerve carried sensation of pain, pressure, heat and cold. The laminated structure of the brain with six layers of nerve cells was recognised by Robert Remak (1815-1865), who besides showing continuity of the axons (nerve fibers) with neurons or nerve cells of the spinal cord, also noted that some nerve fibers were not white (myelinated) but grey (unmyelinated). Camrillo Golgi (1843-1928) developed a silver chromate method of staining neurons which gave the first pictures of the architecture of these cells. Silver salts for reasons yet unknown bind only to the surface of nerves. Theodore Schwann (1810-1882) who describ-

ed the myelin sheath that surrounds most nerve fibers was much influenced by Rudolph Virchow's (1821-1902) cellular basis of disease. Virchow wrote "every animal is a sum of vital units, each of which posseses the full characteristics of life. The character and unity of life cannot be found in one definite point of the higher organisation for example, in the brain of man, but only in the definite, constantly recurring disposition shown individually by each single element" (Bergland, 1986, p 64). Schwann while accepting Virchow's idea that organisms consisted of individual cells which functioned symbiotically argued that brain cells had to know what their neighbours were up to. He conceived of the brain as a gaint spider web with every neuron *directly* connected to every other neuron. His microscopic methods did not allow him to see the synapses (Greek: to clasp) later described by Ramon y Cajal (1852-1934). Cajal, using Golgi's stains, found that every nerve fibre was seperate, ending in tiny bulbs (boutons terminaux) rather like little hands that were *contiguous* with similar bulbs from other axons but lacking any *continuity* between them. But Cajal's discoveries did not lessen the belief in the notion of the brain as a giant-circuit of nerve cells.

More attention was placed on the electricity that flows along the surface of cells than in the activity that went on inside the cell. The synapses became circuit-breakers. Charles Sherrington (1856-1952) who had learnt Virchow's cellular theory in Berlin, continued the work begun by Stephen Hales (1677-1761) 200 years before. Hales had found that the hind legs of a decapitated frog would move if the cut end of the spinal cord was compressed—a type of reflex action. Incidentally Hales made the first direct measurement of arterial blood pressure. Marie Flourens (1794-1867) correctly placed the vital centers of breathing in the medulla, and noted that the cerebral hemispheres received and controlled sensation while the cerebellum co-ordinated body movements. Marshall Hall (1760-1857) showed that reflex action consisted of three parts: a nerve leading from the irritated part to the spinal cord, the cord itself and a nerve going from the cord to the involved body part. Sherrington, known as the father of modern neurophysiology, outlined the sensory nerve supply of the body in terms of the appropriate level of the spinal cord to which the nerve conveyed information about sensibility, and performed several experiments that demonstrated the nature of the tone that is present in normal muscle at rest.

Meanwhile in 1825 C L Nobili's astatic galvanometer increased the sensitivity of measuring electric current by a multiplier effect. Increasing the number of turns made by coil of wire increased the deflection of a magnetic needle when the wire carried electric current. The astatic galvanometer was further refined by William Thompson—later Lord Kelvin—in 1858 into the mirror galvanometer used to receive telegraphic signals. A tiny steel piece, smaller than a sewing needle was suspended by a single fibre. It was a permanent magnet hung at the center of a coil of many turns of wire. When current flowed this tiny magnet swung to one side or another depending on the direction of flow of current. The magnetic force required to turn this needle was very small. A small mirror attached to the needle reflected a beam of light thrown on it onto a screen. The screen had a scale of degrees by which the amount of current in the coil could be measured by the deflection of the spot of light reflected from the mirror. The mirror galvanometer was to be used by Hans Berger in recording the first EEG in 1928. DuBois Reymond (1818-1896) who had built a galvanometer with more than 4000 turns of wire described the resting current seen in excised nerves and muscles and postulated on electromotive force that preexisted in tissues. Edward Hitzig (1828-1907) and David Ferrier (1843-1928) used electrical stimulation to localise the control of body movement by the cerebral cortex. As the recording of electrical potential of the nerves continued Claude Bernard (1813-1878) who demonstrated the paralysing action of the poison curare selectively on motor nerves, spoke of the nervous system as the highest expression of the mileu interior "which inter-connects all the tissues of the organism and makes them react one upon the other" (Spillane, 1981, p 265).

New Tools and Techniques

The latter half of the nineteenth century saw the invention of many tools and techniques now considered essential in medical diagnosis and treatment. Needles and syringes were invented in 1865 (Bergland, 1986, p 39). Herman Helmholtz (1821-1894), who measured the velocity of the nerve impulse, invented the opthalmoscope in 1851. It was now possible to look into the eye, the Shakespearean 'window of the soul'. The swelling of the optic nerves that occurred with brain tumours was observed within a few years, haemorrhage and pallor of the optic discs were also noted. Lister's aseptic surgery and the use of chloroform accelerated the use of surgical techniques; the pocket thermometer was introduced in 1896; Pasteur and Koch established the microbial basis of many diseases and in 1895 Wilhelm Roentgen (1845-1923) discovered the x-ray (De Jong, 1982).

The flowering of clinical neurology also took place during that half-century. In France Guillame Duchenne (1806-1875) who had no formal appointment to any hospitals in Paris, but was allowed to visit outpatient clinics, made major contributions to modern neurology (Dubowitz, 1982). He used electrical methods to study muscle disease, introduced biopsy as a technique in clinical medicine, designed an ingenious needle for muscle biopsy, and described several muscle diseases for the first time including the dystrophy that carries his name. Jean Charcot (1825-1893) founded clinical neurology and psychiatry came into use in the decade of the 1860s when Charcot began his work in earnest. The history of the Saltpêtrière itself serves to highlight the intimate connection between the larger society and the medical world. It was built in 1603 as an arsenal, deriving its name from saltpeter, the principal ingredient of gunpower, that was once manufactured at the site. In 1656 it was converted into a asylum for infirm and abandoned women, in the eighteenth century it housed the 'infirm and insane'. Pinel and Esquirol conducted their psychiatric studies on these hapless victims of France's industrialisation. At the end of the eighteenth century its inmates were described by Coguel as "madwomen seized with fits of violence—chained like dogs at their cell doors and separated from keepers and visitors alike by a long corridor protected by an iron grille; through this grille is pass-

ed their food and the straw on which they sleep; by means of rakes part of the filth that surrounds them is cleaned out" (Foucalt, 1965). In McHenry's laudatory version, "Charcot, who took charge in 1862, saw this motley collection as a veritable mine of neurological material. Containing some five thousand inhabitants of whom three thousand were neurotic paupers and epileptics, the Saltpêtrière offered Charcot a source of case material that was unique in the history of neurology" (McHenry, 1969, p 284). Indeed it did. Charcot described the lesions of multiple sclerosis, motor neuron disease and an inherited nerve disorder now known as Charcot-Marie-Tooth's disease. Charcot is notorious for his role as the charlatan of the Saltpetriere in his preoccupation with hysterical seizures, which according to him occurred exclusively in woman, and which he claimed to cure by compressing their ovaries with his own invention: an ovarian compressor (Veith, 1965, p 232).

In England, Hughlings Jackson (1835-1911), William Gowers (1845-1915) and Charles Brown-Sequard (1817-1894) laid the foundations of clinical neurology at the National Hospital for the Paralysed and epileptic. Jackson is remembered for his seminal work on epilepsy which he defined as "sudden, excessive, temporary discharge" of neurons. He pointed out that lesions of the brain produced a duality of symptoms; loss of function like loss of speech, movement, consciousness and positive symptoms like increased muscle tone, increased reflexes, or uncontrolled motor activity (McHenry, 1969, p 309). Jackson argued for a hierarchical manner of functioning within the nervous system, being heavily influenced by Herbert Spencer's picture of organised societies where primitive lower orders (the spinal cord and nerves and muscles) were kept in their place by the more highly developed upper echelons (the brain). Recent research however reveals that the brain though highly organised does not have a command post at the apex. When Jackson lectured on cerebral function he would draw a pyramid to represent the hierarchy he considered present in the brain. Modern analysis of visual function however shows that neurons of the cerebral cortex operated in parallel not in series. There is no master decision-maker and the brain it seems functions in a democratic and interactive fashion (Ferry, 1986). William Gowers was like Jackson a clinician but differed from the latter's analytical and physiological approach. Gowers was a keen observer of symptoms and signs and described many entities for the first time including myotonic dystrophy, sleep paralysis, and palatal myoclonus.

American neurology began with studies of *Injuries to Nerves and their Consequences* by S Weir Mitchell (1829-1914) who had followed with interest the cases of nerve damage brought forth in such large numbers by the civil war. Mitchell's study of gunshot wounds published in 1864 is but one of a long line of publications and advances in medicine that have occurred through history by the close alignment of the medical profession with the services required of them and rendered by them to the state. As Bernal states "much medical knowledge and pratical treatment was learned in the hard world of the military surgeon" (Bernal, 1971, p 393). From the shaman of yore ordering the rain or sun for the welfare of the tribe to Ambroise Pare (1510-90) unlettered writing in coloquial French about gunshot wounds, Weir Mitchell is but one link in a chain. The United States' Public Health Services' connection with US imperial policy overseas and racism at home is well-documented in Walter Reed's (1851-1902) typhoid and yellow-fever related research following the US occupation of Cuba after the Spanish-American War of 1898 (Bean 1983; Lyons and Petrucelli 1978) and the scandalous study of the natural history of syphilis exclusively in black men, a study that ended only in 1970. (Jones, 1981).

Developments in Physics

As the twentieth century dawned, James Maxwell's (1831-79) electromagnetic theory established a unity between light, electricity and magnetism. Electromagnetic oscillations gave rise to waves in a hypothetical ether, similar to those of light but with much lower frequencies. In 1881 michelson and Morley proved the non-existence of ether. Soon light itself was explained as a low-energy photon or a packet of energy virtually massless moving at an incredible but definite speed. Thomas Edison's (1847-1931) discovery in 1884 of the Edison effect that a glowing filament of an electric bulb could retain a positive but not a negative charge, i e, current would flow only one way from a heated metal plate to a filament, led to the invention of the electronic valve. Electricity could travel without any wires through empty space. In 1905 Lee de Forest (1873-1961) mounted a piece of a zig zag wire between the filament and plate. This electric screen when negatively charged would repel electrons which could not get past this grid. However when the grid was positive or neutral electrons could flow on through to the metal plate. A very small current could change the voltage of the grid—a weak current could control a relatively strong current. The triode was born and with it the revoluntionary possibilities of amplification and of power based on information. Radio and television, high-tension vacuum and valve techniques that followed integrated physics and electricity into the new applied science of electronics.

Cathode ray oscilloscopes provided electronic amplification of very weak signals even very tiny such as occurred between synapses. The Cathode ray tube in which a beam of electrons flashed across a tube on a horizontal axis could be used for on-line recording of a signal on a vertical axis. The string galvanometer, used by Richard Caton (1842-1926) in 1875 to directly record currents from the surface of the brain and 60 years later by Hans Berger, was replaced. It is noteworthy that Berger's publications were initially dismissed as artefacts and his records though carefully assembled were met with "monumental indifference, disbelief or even hostility" (Gloor 1971). Berger's work was ignored for several reasons. Neurophysiologists held a deeply felt belief in the brain as a highly complex neural network. Surely brain activity could not be the simple, regular waves Berger demonstrated. Also, Berger's reticent personality, and his refusal to cooperate in building Hilter's New Order unlike the bulk of the German medical establishment, (Light, 1985) forced him into retirement in 1938 and suicide three years later. Equipment to record EEG was further improved in the United States. Using a recorder developed by Western Union

for writing on a ticker tape with an ink stylus, replacing its magnets with more powerful ones of nickel, aluminium and cobalt alloy and by providing stiffer springs, it was possible to electrically record the human brain's normal background rhythm called alpha waves with frequencies of 8-13 per second at a paper speed of 3/8th of an inch per second. Brain waves would now be recorded easily; the action potentials of individual muscle fibres, and the velocity of nerve impulse could also be studied by using amplifiers and cathrode ray oscillographs.

These advances in neurophysiology made possible by the improved radio and amplifying equipment, oscilloscopes and computers forged in "the furnace of human conflict" during the two world wars, (Walter 1971) were instruments designed for destruction transformed in neurology for more benign purposes. EEG has contributed to knowledge about epilepsy, sleep disorders, brain tumors and altered states of consciousness. But the test has not been anywhere as helpful as the volume of words written about it, well over ten million in the *Journal of Electrophysiology and Clinical Neurophysiology* alone, would suggest (Williams, 1974). Used indiscriminately to bolster physicians incomes, the EEG and EMG have been aptly described as wasteful, and pretentious (Menken and Sheps, 1984); or that as "most single records would best be reported thus: this record departs slightly from accepted standards of normality; nobody knows what this means" (Matthews, 1973). Similar caution has been expressed about the overuse of evoked potential techniques (Eisen and Cracco, 1983). This technique uses computers to store many elicited responses, averaging them and enabling one to record signals as small as one-hundredth of background activity. The electrical route of studying brain function which began in the eighteenth century has done very little for patient care (Bergland, 1986, p 76). Structural abnormalities of the brain are more easily and accurately uncovered by radiological techniques to the development of which we now turn.

As far back as 1838 Faraday had observed a luminous glow which (William Crookes (1833-1919) in 1876 called cathode rays, as they seemed to consist of particles torn out of the cathode or negative end of a highly evacuated glass tube. Nine years later Wilhelm Roentgen noticed something happening *outside* such a tube. It could fog photographic plates, pass through sheets of rubber, through human skin and flesh, but not through bone. Roentgen had discovered x-rays—a scientific discovery with a vengeance (Bernal, 1971, p 73). It unlocked doors in medical diagnosis, and many branches of physics. X-rays are photons with an energy level greater than 100 electronvolts (eV). (For comparison visible light photons have energies of 2 to 3eV). X-ray machines spread rapidly in Europe and the US as the high voltage generators and evacuated bottles necessary to produce x-rays were already available in many laboratories. It soon became clear that x-rays were useful only in differentiating gas from soft tissues and bone. They could not reveal useful structural details in most soft organs like the brain.

The brain posed special problems to clinical medicine. Generally physicians like to visualise the structures they deal with. In addition to vision, physicians till the nineteenth century would palpate, and percuss the part of the body considered involved in disease. However the brain is inaccessible, being surrounded by the rigid bony skull, to the senses of sight, hearing, smell, or feeling, and it is very fragile. Palpating the brain, where there is no skull, would irreversibly destroy brain tissue! Thus the skull which protects the brain from mechanical insults also prevents it from being reached by the physician. Table 1 indicates the presently available means of imaging the brain. Even a quick glance at this table reveals the intimate connection between neuroimaging techniques and usage of some part of the electro-magnetic spectrum (See Table 2). Neuroimaging has advanced because of contributions from many fields of science: neorology, neurosurgery, clinical radiology, radiation and nuclear physics, engineering, mathematics, computer science, mechanical engineering and biochemistry to name a few.

Progress in neuroimaging though rapid was often acciden-

Table 1: Neurological Imaging Techniques*

Procedure	Image of brain that results
Neurological consultation	Imaginary construct of possible pathology
Electroencephalogram	Surface electrical activity below 80 Hz
Skull films	Distribution of crystallized calcium in head
Ultrasound midline	Position of 3rd ventricle
Isotope scan	Distribution of blood-brain barrier
Pneumoencephalogram	Location of cerebrospinal fluid compartment
Cerebral agiogram	Location of blood compartment
Computerized tomogram	Distribution of tissue radiodensity
Positron tomogram	Distribution of brain metabolism and blood flow
Nuclear magnetic resonance imaging	Distribution of brain water

(from Oldendorf, 1980)

Note * All of the special neurodiagnostic procedures mentioned can be considered ways of imaging the brain. Each produces images of the brain in a unique way, isolating some more or less restricted characteristic of the brain and constructing an image from it, thereby providing a restricted conceptualisation of the structure and function of the brain.

Table 2: The Electro-Magnetic Spectrum and Neuroimaging

	Wavelength (centimeters)	Photon Energy (electron volts)	Frequency (Hertz)	Neuroimaging Technique
Radio (upto VHF)	$10\text{-}10^{5}$	0.00001	$10^{3}\text{-}10^{8}$	MRI, Ultrasound
Microwave	0.01 + 10	0.00001 to 0.1	$10^{10}\text{-}10^{20}$	
Infra red	0.0001 to 0.01	0.1 to 1	$10^{13}\text{-}10^{14}$	
Visible	2×10^{-5} to 10^{-4}	1 to 6	$10^{14}\text{-}10^{15}$	
Untra violet	10^{-7} to 2×10^{-5}	6 to 1000	$10^{16}\text{-}10^{17}$	
Xray	10^{-9} to 10^{-7}	1,000 to 100,000	$10^{18}\text{-}10^{20}$	Skull xrays Computerised tomography
Gammarav	10^{-9}	100,000	$10^{21}\text{-}10^{22}$	Radioactive Isotope

(modified from Oldendorf 1980; Weinberg 1977; Young 1984)

tal. In 1912, an x-ray taken of a man with a skull fracture showed air in the cavities or ventricles of the brain. Six years later, Walter Dandy (1886-1946) "made the quantum intellectual jump from the clinical observation of air in the head resulting from head trauma... to its deliberate injection for diagnostic purposes" (Oldendorf, 1980, p 15). The pneumoencephalograph or PEG, used for over 50 years did not show the brain directly. Air injected between the middle (arachnoid) and inner (pia) layers of the coverings of the brain filled the ventricles of the brain and by comparing differences with a normal outline one could infer something about the size and shape of surrounding structures.

A Parisian neurologist Jean Sicard (1872-1929) had been using Lipiodol, an iodized oil for treating back pain. He injected the substance into the lumbar muscles and found that it was well tolerated and produced no serious side effects. He had noticed that Lipiodol was excellent x-ray material and used it to outline the bronchial tree in the lungs. One day one of his pupils injected Lipiodol into the lumbar muscles and was horrified when he found he was withdrawing cerebrospinal fluid (CSF) as he drew back the plunger of the syringe. He rushed off to Sicard, who asked how the patient was and on being told the patient was well, decided to look at the lumbar region on a flourescent screen. Sicard first screened the patient standing up and saw that the Lipiodol had dropped to the bottom of the cavity surrounding the spinal cord (the spinal subarachnoid space). He then had the brilliant idea of tilting the patient head down and seeing the movement of Lipiodol (Bull, 1982). The technique of myelography was born, one which has proven very useful in diagnosing diseases of the spinal cord-like tumors and protruded intervertebral discs. In 1926 Egaz Moniz (1874-1955) performed the first cerebral angiogram in a living patient. A substance opaque to x-rays was injected in the carotid arteries that supply blood to most of the brain. This technique, still in use today, delineates tumors, hemorrhages, blood clots and vascular malformation of the brain. Research now concentrated on the development of a non-toxic contrast-agent. These agents had to confront the blood-brain barrier (BBB) which depends upon certain characteristics of the capillaries in the brain. A capillary, a tube with a diameter of 0.1 mm, length of about 1 mm has a wall of single flat endothelial cells that are about 0.001 mm thick. Blood and soluble substances in the plasma can pass through the walls of non-neural capillaries or diffuse through the intercellular clefts, or pores between two endothelial cells. Molecules up to 40,000 molecular weight can pass through these pores. Pinocytosis is another way of bloodcell exchange. Here the inner walls of the endothelial cell breaks, a small amount of blood enters the cytoplasm and is transported through the width of the cell and dumped into the extracellular space immediately surrounding the capillary. In neural capillaries, on the other hand, there is no intercellular cleft, the endothelial cells form 'tight junctions', and pinocytosis is virtually absent. Thus the blood and brain can exchange material only through the capillary cell. The tight junctions exclude molecules with molecular weights as low as 2000. Water-soluble polar compounds, i.e. those substances which have an electric charge at each end of the molecule, are mostly excluded while lipid-soluble compounds rapidly and easily enter the brain. Paul Ehrlich (1854-1915) had discovered the BBB in 1885 when he noted that aniline dyes injected into an animal stained its body but not the brain or spinal cord. The BBB is 'lost' when the brain suffers any kind of insult like infection, trauma, or a stroke.

The contrast-agents that became widely used were iodinated organic compounds because they were the least toxic, stable in water-solution, with a high molecular weight, but low osmolarity, (1.5 osmolar solution only five times the 0.3 osmoles of brain capilary endothelial cells). Also the iodine atom's innermost shell of electrons (the k-shell) has a binding energy of 33 Kev. Incoming x-rays in computerised tomography have an energy level of 60 to 80 KeV. These rays can be captured by the k-shell electrons of iodine, deleting the x-rays and increasing the radiodensity of the tissue that contains it.

The second world war which sparked the development of nuclear physics resulted in many artificial radioactive substances being avaialble by the mid-40s. In 1947 George Moore then an intern in surgery discovered that radioactive iodine injected intravenously emitted gamma rays which could be detected by a Geiger counter. Radioactive isotope imaging was refined in the next two decades using a thallium-activated sodium iodide crystal photo multipliers. The small amount of thallium breaks up the regularity of the sodium iodide crystals so that they scintillate or generate visible light photons when struck by gamma rays. These photons are amplified by the photomultiplier and the amplitude of the voltage thus produced measured electronically. Radioisotope scanning did not produce sharp images of the brain as attempts to sharpen the image by collimation resulted in many emitted rays being uncounted. Also Compton scatter or deflection of gamma rays by atoms in their path made the rays appear to have a different origin when they reached the detector, these 'incorrect' locations further contributing to a fuzzy image.

Visualising the Brain

By 1971, though the brain could be visualised indirectly by angiography, ultrasound, radioisotope scanning, PEG etc, these tests were either cumbersome, time consuming or very uncomfortable to the patient. W H Oldendorf around 1960 and G N Hounsfield in 1967 independently developed the technique of computerised axial tomography (tomos=a slice) based on tissue specific gravity. The fascinating story of the development of computerised tomography is recounted in Oldendorf's book *The Quest for an Image of Brain*. In 1960, Oldendorf applied for a patent for a device that produced a radiographic cross-section of the distribution of tissue structures based on regional radiodensity. A narrow collimated beam of high energy photons passed through the head and were counted after they emerged from the head by means of a detector fixed in relation to the photon source. Several points on a particular plane of the head were scanned using rotational and translational motions. The observed counts of photons were then processed by a computer which reconstructed the distribution of radiodensities within

the plane. Oldendorf was granted a patent in 1963 but found none of the major x-ray manufacturers interested in the device. As he ruefully remarks "their lack of interest was a matter not so much of technical unfeasibility (since they had more information than I had as to whether the idea was workable), but more of economic promise. A letter from one of the world's major x-ray manufacturer ended—even if it could be made to work as you suggest, we cannot imagine a significant market for such an expensive apparatus which would do nothing but make a radiographic cross-section of a head" "Oldendorf, 1980, p 85-6). Success came to Gordon Hounsfield who worked in the research laboratories of EMI Ltd. Hounsfield decided to use sodium iodide crystals rather than the photographic plates used for 50 years in radiology, because the crystals being 100 times more sensitive than the plates, allowed better differentiation of soft tissue density. As his device took five minutes to produce a picture he was advised to study the brain which did not move rather than the chest or abdomen as images produced of these regions would be blurred since no patient could hold his breath for five minutes. Today a picture can be produced in seconds allowing any part of the body to be scanned.

EMI pursued the development of the CT scanner as Oldendorf explains, being previously uninvolved in medically-oriented research they were not aware that the limits of technology had already been explored. The production of the CT Scanner illustrates a feature common to technological and scientific advancement under capitalism. The large x-ray manufacturers behaved in a manner similar to wireless manufacturers: too intent on immediate profits to indulge in expensive development (Bernal 1971, p 717) whereas the unorthodox approach of the inexperienced musical company led it to market one of the truly revolutionary diagnostic techniques in medicine. Two other brain imaging techniques have become available since 1971. They are positron emission tomography (PET) which measures regional metabolism of glucose or oxygen and magnetic resonance imaging (MRI) in which the magnetic property of hydrogen atoms is utilised. The hydrogen atoms of the brain are made to resonate in a strong magnetic field. They partially align themselves with the field and absorb energy which is subsequently reradiated. Images of hydrogen density and relaxation time allow striking pictures of the brain and spinal cord making virtually all parts of the central nervous system accessible to the human eye without tissue ionisation, injection of contrast material or radioactive substances being involved (Oldendorf, 1984).

C T and MRI scans have proliferated in the US, the number of C T scanners rising from none in 1973 to 800 in 1978 representing a capital investment of 400 million dollars (Oldendorf, 1980), while MRI scanners rose from none in 1978 to about 200 in 1985 leading the industry's two dozen firms collectively looking to annual sales worth 2500 million dollars worldwide in 1988 (*Lancet* 2:1169, 1984). Separate buildings, each costing as much as 1.5 millions dollars, have been constructed to 'contain' the magnetism surrounding the MRI equipment financed by 'venture-capital' groups who see them as tax shelters or investment opportunities (Goldsmith, 1984).

So the high-tech revolution in medical diagnostics is expensive, becomes obsolete rapidly and by virtue of the financial stakes involved, available at a stiff price therefore largely only to the affluent (see Table 3). Though the technology provides diagnosis more accurately at a crucial early stage of some diseases, and the greater precision of pinpointing lesions leads to a reduction in other tests (see Table 4) it is cost-effective in a rather narrow sense: to those able to get the test done. The issues of cost-effectiveness deserves a full discussion on its own. Suffice to say here that in the US corporatisation of health care promotes the use of capital intensive technology while ignoring the question of access to these services by the 35 million Americans who are either under and uninsured.

Improvements in neurodiagnosis aided the growth of neurosurgery. Injury to the head had been regarded as a surgical problem since antiquity (Flamm, 1982), but removal of tumors of the brain and spinal cord was first attempted only about a century ago. Victor Horsley (1857-1915) a pioneer who contributed to many neurosurgical techniques

Table 3: Costs of Various Neurodiagnostic Procedures in Relation to Discomfort to Patient, and Information Obtained

Procedure	Discomfort form Procedures	Information Obtained	Cost (US Dollars)
Neurologic Consultation	—	+++++	80-100
Skull xrays	—	+	55- 75
EEG	—	++	75-150
Ultra-sound (midline ECHO)	—	+	25- 50
Pneumoencephalogram	++	++	300-500*
Caroted angiogram	++	+++	550-1200*
Digital Subtraction Angiography	+	++	300-400
Radioisotope Scan	–	+++	150-250
C T scan (head)	–	++++	300-500
C T scan (spine)	–	++++	325-600
MRI scan (head)	–	++++	600-800
MRI scan (spine)	–	++++	600-800

Note: * If costs of hospitalisation are included these procedures would me much more expensive—daily room charges vary from $ 175-250 1 day.

(modified from Oldendorf 1980; Gunby 1983)

Table 4: Effect of Various Procedures AT Dent Neurological Institute, Buffalo, N Y

Procedure	1973 (pre-CT)	1976 (post-CT)
Echoencephalograms	189	0
Pneumoencephalogram	39	5
Isotope brain scan	579	157 (16)*
Lumbar punctures	425	167
EEGs	1,047	731
Angiograms	111	87
Hospital admissions	355	351
Patients seen in ER	222	291
Office consultations	668	1,087

Note: * Sixteen tests were required by neurosurgeons and neurologists. The numbers below the line indicate that, despite the reduction of tests, the total clinic work load increased between 1973 and 1976.

(from Oldendorf 1980)

including decompressive surgery for brain tumors, laminectomy for removal of spinal cord tumors, nerve section for relief of exquisite facial pain (tic doloureux), etc deserves mention for his championing of social causes. He was an aovwed agnostic who worked for Votes for Women (the Suffragette Movement) demanded equality for women in medicine, sought proper recognition for the nursing profession and urged health legislation that would benefit the poor (Cooper, 1982). He was disliked by the British medical establishment who feared his socialism (Taylor, 1986). A remark of William Osler's illustrates the attitude of the medical establishment then (and I suspect it would not be very different today) to Horsley's politics: "What demon drove a man of this type into the muddy pool of politics?" (Osler, 1916). Horsley though appointed to the staff of the National Hospital in 1886 was given no beds of his own in the thirty years he worked there.

Neurosurgery progressed rapidly in the twentieth century keeping pace with developments in neuroradiology. Harvey Cushing (1864-1939), a leader in modern neurosurgery, investigated the role of the pituitary gland and established that it secreted growth hormone. He linked the brain with endocrine function, a link that appears increasingly important as the number of neuropeptides discovered grows, their actions playing a pivotal role in memory, emotions, sleep, and the perception of pain. Indeed Bergland (1986) argues that we have come full circle. The brain may be what the Greeks imagined it to be: a hormonally modulated gland with the "stuff of thought" being large molecules or peptides and not electricity. The discovery of neuropeptides would have been difficult without a simple and safe technique to examine cerebrospinal fluid (CSF). Such a technique was invented by Heinrich Quincke (1841-1922) who was searching for a way to remove CSF from children with hydrocephalus. He inserted a needle with a stylet in the lumbar intervertebral place and removed CSF. He used the lumbar puncture to examine the constituents of CSF and described the changes in the latter in purulent meningitis (McHenry 1969, p 366).

The role of special chemicals or neurotransmitters that conveyed messages across a synapse was first described by Henry Dale in the 1930's. Acetyl choline, released by the vagus nerve which supplies the heart, slowed the rhythm of the heart. Soon other neurotransmitters were discovered and by 1975 it was known that the brain produced morphine like substances or endorphans. Presently over 45 neuropeptides are known and their effects on degenerative diseases of the brain like senile dementia and Parkinson's disease under active study. Tools used in peptide research include radioimmunossay, immunocytochemistry and complementary DNA probes. Usage of monoclonal antibodies, introduced in the last decade, has made possible knowledge about the internal structure of the neuron. Disciplines that were unknown till the early seventies flourish in their own right today. Neuroimmunology, molecular genetics and neuropeptide research bring together branches of science outside the field of clinical medicine. Advances in knowledge are depandant upon a sophisticated and wide technological base. Often new techniques are developed for reasons other than what they are used for later. For instance monoclonal antibodies developed out of Milstein and Kohler's attempts to learn more about the genetic control of synthesis of antibodies (Sattaur, et al, 1984). Presently brain function is accepted as both hormonal and electric, without a brain-body dualism. Both are dependant on and influenced by the other. A basic operation or function common to all areas is suspected but the manner in which integration of thought and behaviour occurs is unknown. Neither are we able to correlate structure and function at the level of a single cell (Philips et al, 1984).

Conclusion

The brain then remains the enigma it has been through millenia. It can however be visualised, directly and indirectly, its functions studied and modified by chemical, electrical, and surgical means. Progress in medical technology and knowledge about basic biologic structure and function, which permit these interventions in the nervous system, records even more spectacular advances in other organs—the heart, the liver, the kidney and bone marrow can be transplanted. Machines can do the job of the heart, the lungs and the kidney. No part of the gastrointestinal tract remains hidden from the human eye with the use of fibre-optics. Setting broken bones, stitching up torn arteries, controlling bacterial, fungal and parasitic infection, these are but some of the techniques taken for granted by a majority of the citizens of Europe and North America. But the availability and relevance of this technology to a large section of humanity remains tied in to the social, philosophical and economic realities which govern our planet. Flowering first in Europe, and later North America, medical technology has concentrated on a cellular and clockwork like approach to the body. Preventive measures have generally received scant attention particularly those that focus on industrial pollutants as likely carcinogens or of individual habits like smoking that are promoted by big corporations. Prevention by innoculation against disease no longer has universal applicability.

Recently developed hepatitis and malaria vaccines are enormously expensive and intended only to aid soldiers of the "free world" as they are called to save democracy in tropical and equatorial climes. The electronic razzmatazz available at the beck and call of physicians follows the road of most commodities—the more, the better! Marketed expertly by companies out to make quick and big profits much of the application of medical technology is prohibitively priced and even unnecessary (Angell, 1985). Certainly it is difficult to account for the number of intensive care units, CT scanners, coronary artery bypass grafts in the United States without considering the links between medicine and the health care industry.

A society that cares neither for adequate prenatal care, nutriton, education, housing, and old-age security exhibits sudden concern for end-stage renal disease and elderly patients when government programmes assure physician, hospitals and biotech industries of sustained high income. A modern intensive care unit reflects uncannily the society from which it has emerged. Notwithstanding the underlying disease, modern death bed rituals are mounted. Every index of body function is tracked and treated without any

attempt at considering the patient's prognosis or the futility of these costly heroic efforts. Blood gases, body pH, electrolytes, urine output, continuous electrocardiographic monitoring and arterial blood pressure recording, respirators, nothing is ignored in this relentless pursuit of information.

Macabre though it may sound, patients die, but not before they are made biochemicaly and haematologically normal! The same system of hospital based technological intensive medicine is sought worldwide, an acknowledgement in part of its limited, but definite success in combating disease and relieving suffering. The control of infection proudly acclaimed as an achievement of medicine probably has more to do with better nutrition, sanitation and hygiene (McKeown, 1976). The efficacy of antibiotics has depended on the integrity of the body's defence mechanisms against disease. They are ineffective in infections such as the AIDS virus, which derives its lethal nature from its ability to destroy the immune system of the body. The AIDS epidemic illustrates the complex multifaceted nature of modern medicine. Though the medical establishment is baffled by the disease and presently unable to help its victims adequately, a remarkable amount of knowledge has been acquired in the five years since the disease became known. The medical profession not particularly noted for its compassion towards those society rejects or ignores, has been free of panic and prejudice while AIDS high risk groups consisted largely of drug addicts and male homosexuals. In fact, it has campaigned against hysterical and unwarranted measures such as quarantine very effectively. Medical technology helped uncover the human immunogenic virus as the cause of AIDS and may give us a vaccine in the next decade. Yet AIDS illustrates the limitations of modern medicine. It concentrates on treating disease not in learning more about why only a few acquire it. In any epidemic the disease affects a much larger proportion of the populace than is either incapacitated or killed by it. Factors that protect most individuals are only now beginning to be studied.

Finally and very importantly comes the question of resource allocation. It would cost a fraction (about 30 billion dollars) of the amount spent on arms (800 billion dollars a year) to feed, clothe and educate every person on earth. CT scanners and MRI equipment co-exist within a stone's throw of people scouring through garbage cans for food. Drugs that can save human lives are controlled by corporations notorious for overcharging poor countries. As Martin Ryle put it in a letter written several months befor his death in 1984: "The benefits of medical research are real, but so are the potential horrors of genetic engineering and embryo manipulation. We devise heart transplants, but do little for the 15 million who die annually of malnutrition and related diseases. Our cleverness has grown prodigiously—but not our widsom" (Ryle, 1985).

Politics of Contraceptive Technology
Depo-Provera in New Zealand

sally washington

The development and dissemination of injectable contraceptives provides a good illustration of the politics of contraceptive research and its international dimensions. It is also an example of the capitalist patriarchal control over women's fertility. The article throws light on the $ six million clinical trial which was conducted in New Zealand by Upjohn, the sole manufacturer of the contraceptive. Needless to say a majority of women on whom the drug was tried were black and working class as well as Maori women. The New Zealand trial was extremely important to the manufacturers for several reasons and moreover there were several conditions in the country which made it convenient for Upjohn. Not surprisingly women's struggles against these trials have been determinedly put down.

IN the patriarchal mode of reproduction, women lose their social power at the moment of conception when the work of reproduction begins. There is no right time to become pregnant because in this mode, sex, procreation and the socially necessary work of parenting are inextricably linked and all occur under male control. (Trainer, 1986). In theory however, contraception allows individual women to plan when they will confront this process. Female control of fertility is therefore an essential condition of women's self determination and is an important site for gender struggles.

Women do not make real choices about when or whether to reproduce. It is a misnomer to talk about 'free choices' when the means of contraception (the pill, injectables, intra uterine devices [IUDs] etc) are not primarily developed according to women's needs, but are determined by the forces of the capitalist patriarchy mediated by the state, the medical establishment and the multinational drug corporations.

In this article I examine the patriarchal means of contraception to discover the real relations behind their development and dissemination. I shall use the example of the injectable contraceptive Depo-Provera as one of the most horrific examples of the capitalist patriarchal control of women's fertility, and one that has special relevance for New Zealand women. I shall also attempt to link this discussion to the current struggle by Indian women to have a similar (progestogen based injectable) contraceptive, Net-Oen, banned in their country.

A Patriarchal Industry

Men dominate the contraceptive industry at every level; in research and development, as manufacturers and suppliers, and as regulatory authorities. Male dominance means that the contraceptive cafeteria reflects patriarchal needs to control female fertility. Common features of 'modern' contraceptives, are that they control female rather male fertility. The form that their administration takes, is that birth control is a female responsibility. Virtually no research has gone into male contraception. The repertoire is currently limited to condoms and sterilisation, as patriarchy could not tolerate tampering too much with male fertility.

Birth control is also a commodity. The forces of patriarchy determine that contraceptives should be aimed at female fertility, but the detailed decision about which contraceptives will be developed are determined by the forces of capitalism. The bulk of research money pours into IUDs, the pill and methods of 'reversible' sterilisation including injectables, while barrier methods receive minimal investigation. Barrier methods have limited profitability whereas chemical methods are "amongst the most profitable of all pharmaceuticals" (Bunkle, 1983).

Chemical methods are presented as more 'effective' but the real reason why they are given such priority is because they are administered by medical professionals, not controlled by the women who use them. Chemical methods are typically dangerous so women must be kept ignorant of their functioning.

The patriarchal monopoly of contraceptives and contraceptive information means that women must either 'accept' whatever is developed and offered by patriarchy and risk dangerous side effects, or 'fall' pregnant and face a possible lifetime of domestic drudgery. The social conditions of our lives and the wider political system in which we live influence the extent of risk we will take as well as the awareness of that risk. In countries like India, a women's ability not to become pregnant often means better access to housing, schooling for their children and health services: all typical family planning incentives, (Balasubrahamanyam 1986).

While modern contraceptives appear to give women some choice about when they reproduce, the real structures at work are patriarchal and hence, do not serve women's needs. Capitalist corporations require that contraceptives maintain profitability, imperialist nations require effective population control weapons and the medical profession demands that contraceptives are monopolised so that only medical 'experts' can administer them. Under these criteria, Depo-Provera and its injectable cohorts are ideal contraceptives.

Depo-Provera in New Zealand

Depo-Provera works by inhibiting ovulation and is administered by injection once every three months. It is however, a temporarily irreversible drug which cannot be purged from the bloodstream once injected. Those women then, who suffer severe side effects from it must endure these for at least three months. Millions of women are using Depo-Provera worldwide which given its dubious safety record, amounts to a massive experiment on women, (Bunkle, 1985). Since the patent on DMPA, the progestogen used in Depo, expired in 1984, other brands of injectable contraceptives have flourished. One of these is Net-Oen. Given that the active agent in progestogen-based injectables is similar if not identical to Depro-Provera, it could logically be argued that the side-effects will also be similar. Certainly the means by which multinational corporations have 'tested' and disseminated their particular brands have been surprisingly similar.

America's Upjohn Corporation took over the development of Depo in the 1960s. The drug had been used in the 1950s

but had been cast aside because it caused disease of the uterus (Unity, 1982). In 1965 Upjohn researches began human experiments on Thai women using three monthly doses of Depo which were later increased to six monthly doses.

In 1969 Upjohn applied to the American Food and Drug Administration (FDA) for a licence to sell the drug as a human contraceptive. A year later, the seven year study on beagle dogs and the eleven year monkey study required by the FDA began. In New Zealand the Health Department approved Depo Provera for use as a contraceptive before the results of both studies were released. The results revealed increases in both benign breast nodules and breast cancer. Meanwhile, other unsuspecting women were participating in trials of Depo in Bangladesh as were black women in South Africa and what was then Rhodesia.

In 1974 the FDA allowed the 'restricted' sale of Depo for 'patients' who knew the drug could make them sterile; who were unreliable users of contraceptives; who could not use other forms of contraception; or who had a history of contraceptive failure. In 1978, after three Congressional Hearings the FDA rejected Upjohns's application to market the drug in the USA.

A year later, the rhesus monkey study revealed that two out of the twenty high dose animals had cancer of the uterus and three had breast lumps. But Upjohn's enthusiasm was not dampened by these results.

Many developed countries including Australia, Britain (temporarily) and the USA have banned Depo pending proof of its safety. Evidence is still being gathered from millions of female 'guinea pigs' who still use it: essentially the poor in Jamaica, Thailand, Mexico, Sri Lanka and New Zealand. In countries where it is banned for general use disadvantaged sections of the population are also using it, in particular: West Indian and Asian women in Britain, aboriginal women in Australia and Chicano and Black women in America. Similar trials of other injectables with less of an international reputation then Depo are also being conducted, such as the Net-Oen trials in India.

The carcinogenity of Depo has been the main issue in the debate over its safety. Other side effects are relegated to 'minor' or 'irrelevant' status, which women are expected to put up with. What are the effects of Depo use?

i) Long-term risks include:

a) anemia
b) diabetes
c) temporary or permanent infertility
d) uterine disease and permanent damage to the ovaries, pancreas, liver and adrenals
e) lowered resistance to infection because of its negative effects on the production and distribution of antibodies: particularly damaging to poor women.
f) child abnormalities: Depo is especially recommended for breast feeding mothers on the assurance that there are no negative effects on the production of breast milk. Yet Depo has been found in breast milk, and discovered in the fact tissues of breast fed children of Depo mothers. The drug also cannot be discontinued if a women finds she is pregnant which means it could act on the fetus for several months.
g) cervical, endometrial and breat cancer: Depo users have revealed three to nine fold increases above normal rates of cervical cancer (Neal, 1979).
h) A New Zealand study found that several women had serious anaphylactic reactions which were almost fatal (Bunkle, 1983).

ii) Immediate and short-term effects include:

a) abdominal discomfort
b) dramatic weight gain or loss
c) depression: progestogen is a well-known depressive drug.
d) loss or suppression of sexual desire and/or orgasm: Depo is used in two American clinics to chemically castrate rapists. Supressing libido is an ironic property for a contraceptive.
e) headaches, dizziness and nausea.
f) vaginal discharge
g) breast discomfort and abnormal growth
h) menstrual abnormalities are suffered to some extent by all women on Depo.

One respondent to a New Zealand survey was bled every day for three years and eventually had a hyserectomy, while about one Depo user a week is admitted to Auckland's National Women's hospital with uncontrollable bleeding. Yet Upjohn medical director, Norman McLeod, dismisses this by saying "Anyway, bleeding is more of a nuisance than a health problem and can be easily dealt with" (*The Press*, 1985) apparently by administration of controversial estrogen pills probably also produced by Upjohn.

Depro-Provera was not primarily designed to help women control the reproductive lives, so why do millions of women still use it? Probably the main reason why women still use drugs like Dempo, despite their dubious safety records, is that they are not aware of the risks or the alternatives. We assume that whatever medical professionals and 'specialists' prescribe has been adequately tested and proved safe. This assumption could be fatal.

Scientifc Evidence

The FDA ban on Depo effectively closed the US market to Upjohn and worse still meant the US 'aid' agencies could not supply it overseas. Upjohn has campaigned hard to have this situation reversed. The most effective strategy in this campaign has been to produce 'scientific evidence' that the drug is safe. It has spent millions a year ($ 6 million on a New Zealand study alone) on research designed to produce the desired results. Investigations into the safety of Depo have therefore centred on its carcinogenity (which is difficult to prove anyway) while its more immediate side effects have been ignored.

Upjohn's control of the information about Depo allows it to brush asise any evidence that questions its safety. In the first seven-year beagle study for example, Upjohn dismissed the findings that 18 of the 20 dogs receiving Depo died, by claiming that beagle dogs were especially prone to breast tumours.

The results of the rhesus monkey study were similarly dismissed by saying they were dose related. Upjohn's claim that Depo "is probably the safest harmonal contraceptive

drug available" is therefore totally unproven (Bunkle, 1983). So while medical practitioners may prescribe it in good faith, their decisions are based on mis-information produced and controlled by the company that stands to profit.

And profit it has. The first Reagan administration passed the Drug Regulations Act which rendered impotent the FDA ban on Depo sales to the Third World. Drugs judged unsafe for Americans can now be exported provided they are requested by the foreign government. Apart from Upjohn's profits, the assault on Third World women has other advantages:

"Population explosion, unless stopped would lead to revolutions: population control is required to maintain the normal operations of US commercial interests around the world... without our trying to help these countries with their economic and social development, the world would rebel against the strong US commercial presence. The self interest thing is the compelling element" (Ehrenreich, 1980).

Government applying for loans from organisations like the World Bank (with heavy US presence) are usually required to show that they are addressing their 'population problem'. Sterilisation programmes and campaigns of Depo-Provera and other injectables are pushed because they are immediately effective with long-term results.

Why New Zealand?

US imperialism concentrates Depo's three-way assault of racism, patriarchy and capitalism. Like other weapons in this armoury, Depo has been aimed at women in New Zealand.

In 1968, the New Zealand Health Department approved Depo for use as a contraceptive, before the study on its effects were complete and despite its ban in the US. Moreover, it is offered as "one of the many available choices" (Bonito, 1980) rather than approached conservatively.

There are several reasons why Upjohn has chosen to study women in New Zealand:

First, they reveal the highest rate of Depo use for a population whose social and ethnic composition resembles that of the US, where the company ultimately hopes to market the drug.

Second, the subsidised health system here is a great boon because it relieves the company from having to pay for any medical treatment required by women involved in the study.

Third, the ACC (Accident Compensation Corporation) Act absolves Upjohn of all damages suffered by the women. Drug companies have had to pay millions of dollars in the US in damages for the effects of drugs like Depo.

Fourth, since the New Zealand Medical Association monopolises and the state regulates the dissemination of contraception, the company does not have to seduce a wide variety of organisations.

That the power brokers—state and medical—are united in supporting the Upjohn study means the assault on New Zealand women will continue. But the Depo-Provera assault is not distributed evenly. There are definite targets.

In New Zealand, Depo is administered mainly to women who have the least access to contraceptive information; women for whom informed consent has little relevance. For example:

1) One survey revealed that 42 per cent of Maori women and 11 per cent of Pakeha (European) women had used Depo while another concluded that the injection was the only contraceptive method used by a higher proportion of Maori women than European women, (Bunkle, 1982; Trlin and Perry, 1981). This reveals racist attitudes on the part of white middle class medical practitioners who view Maori women as unreliable users of contraception.

2) Working class women—one study discovered that the injection had been used by a higher proportion of women without school certificates and by women whose partners were in the 'lower' status category (Trlin and Perry, 1981).

3) Maternity patients and breast-feeding mothers—one study found that some women were given Depo as routine medication before leaving the maternity hospital and were assured that it would not alter the milk supply. Many were not told what they were being given until it had been administered but being in unfamiliar surroundings and subject to hospital rules they were not in a position to resist or complain.

4) Mental patients and intellectually handicapped women are given Depo on the excuse that menstruation is a 'problem' for hospital staff. This totally ignores the fact that instead of losing their periods some women 'flood' while on Depo. In addition a women admitted to a psychiatric institution, perhaps suffering from some form of depression, "should not be subjected to a drug known to cause depression" (Clark, 1980).

Depo is also given to young women who are considered 'sexually irresponsible'; to immigrant women especially if they are of an 'undersirable' type (i e, non-European); and to post-abortion women.

But by far the largest group using Depo-Provera however, are Black and working class women. Health professionals say this is because these women like Depo and cannot or will not use other forms of contraception. The reality is that women do not make choices about their reproductive lives under conditions that they control.

Black and working class women are under great preassure to accept stronger and more dangerous methods of birth control because an extra child could have quite disastrous effects on the quality of the lives of existing family members. When family planning incentives and dis-incentives are institutionalised as they are in some countries like India these pressures are even greater.

In a capitalist society doctors set up in areas where they can earn most, which means that women living in working class areas see doctors who are typically overworked. Quite apart from any decision those doctors may make about the contraceptive competence of any individual woman, they simply do not have the time to explain various contraceptive methods adequately.

Women are dependent on those who control the goods and the information. One New Zealand study found that 82 per cent of Depo users should not have taken it had they known the evidence against it (Amas, 1984). In India a Net-Oen camp was disrupted when half the women left after hearing about the dangers of injectable contraceptive use (Nair and Balasubrahmanyam, 1985). Women appear to 'consent' to

using dangerous contraceptives but what appears as consent is really submission.

Their 'decisions' are largely determined by the material conditions of their lives including their access to abortion facilities, their ability to support another child and by the limited information they receive from the birth controllers.

Contraception is an important area for gender struggles because as long as men control women's fertility, female sexuality and the work of reproduction will be inextricable linked. What forms have women's struggles against injectable contraceptives taken and how effective have they been?

Women's Struggle Against Injectables

The campaign against Depo was an attempt by New Zealand women's health groups to have the Upjohn study stopped and Depro-Provera banned in New Zealand. By publicising the side-effects of Depo use it was hoped that women could resist being manipulated into participating in the study and or using the drug. But the feminists who campaigned against Depo have been verbally attacked, threatened with libel suits, or dismissed as 'emotional' and 'hysterical'. Upjohn was not about to waste the $ 6 million it had pledged for the study.

The study's essential aim is to produce data that will extend the Depo-Provera stranglehold. Not long after the study began Upjohn was claiming the success of its New Zealand study and claiming that it proved the drug's safety for use in America.

And while even statisticians and demographers criticised the study's protocol they have never been given the opportunity to back up their arguments with the data from the study because this has never been made public (*The Press*, 1983). Completed questionnaires go straight to Upjohn's New Zealand headquarters then directly, without being opened, to Michigan, USA, where data is stored on their company computer. Only Upjohn scientists have access to that data. The 'facts' that are concluded from the study will reflect the male-dominated and profit-oriented structures that created them. The opinions of lay women have no status alongside those of the country's medical experts. The $ 6 million Upjohn was prepared to pay for the study is equivalent to the entire budget of the New Zealand Medical Research Council and must have been an irresistible attraction to those experts.

For women's groups, the struggle was diverted to the more immediate and probably winnable Dalkon Shield crisis. The anti-Depo campaign essentially failed, alongside rumours that new injectables are being secretly trialed at our top medical institutions.

It is interesting for New Zealand women to see the successes of our India sisters in the struggle to ban Net-Oen in their country. Perhaps this is because in contraceptive camps women do not confront the drug or the administrators of that drug alone, but can stand together for a collective refusal as in the example of the Net-Oen camp described above.

But despite the success and failures there are several points that need to be remembered:

Women should struggle against all 'types' of contraceptives rather than certain brands. The adverse publicity created about Depo had no effect on the development, trials and dissemination of similar injectables marketed once the patent on Depo was lifted. The same was true of the Dalkon Shield debate: other potentially dangerous IUDs were left with their reputations intact.

It is also important that women share information across international boundaries and link our struggles so that getting rid of a dangerous contraceptive in one country does not mean that the problem is simply exported to more vulnerable women in some other country.

Perhaps the most effective strategy, and one that has ramifications for women outside the birth control arena, is to empower individual women or groups of women to stand up to the birth controllers. Empowering women means providing them with information to challenge the 'wisdom' of doctors, medical 'experts', technicians working in contraceptive camps and 'scientific evidence'. Information is power and both must be shared for women to take some control of their reproductive lives.

Work, Ideology and Science
The Case of Medicine

vicente navarro

This article discusses the nature of work, ideology and science in Western capitalist societies. It analyses how capitalist or bourgeois ideology reproduces capitalist dominance in the spheres of production (Section I), politics (Section II), and science and medicine (Section III). Also, this article explains how the working class responds to that capitalist dominance through a continuous process of class struggle. Sections I, II and III show how class struggle affects bourgeois dominance in the processes of production, politics, and science and medicine, respectively. Special focus in Section III is on the analysis of (A) how bourgeois dominance appears in science and medicine; (B) how bourgeois ideology appears and is reproduced in medical knowledge; and (C) how class struggle determines the nature of scientific and medical knowledge. In this section, an alternative mode of production of scientific and medical knowledge, different from the prevalent bourgeois one, is presented and discussed. In all three sections, medicine and medical knowledge are chosen as the primary points of reference.

The article is reproduced from *Social Science and Medicine*, Vol 14, C no 3, 1986.

"The docs keep telling me there's nothing wrong with the place where I work, I guess they are supposed to know it all because they have had a lot of education and everything. I'm no expert like they are, but I sure as hell know there's something wrong in that mill and other guys are saying the same thing. One thing I know for sure—that place is killing us." — Cancer patient and steelworker from the Bethlehem Steel Corporation mills, Baltimore, Maryland, USA, 1978.

THERE is a concern among the centers of power in the Western capitalist world that something is going wrong with the nature of work in that world. Editorials in the daily press, articles in scholarly papers, reports of powerful foundations, exposé programmes on television, and even more recently, some commercial films have focused on different dimensions and components of what has been called the 'crisis at the work place' in contemporary society. Part of this crisis is the rebellion of the working populations against their conditions of work, rebellions which appear in different forms such as absenteeism, turnover, or just plain sabotage. These have reached such proportions as to become a cause for major alarm by the establishments of those societies. An example of this concern and alram is one of the reports of the powerful Trilateral Commission. A major recommendation of that Commission, which includes representatives of the power structure of the top capitalist developed societies [1], is that "a major intervention is required in the area of work in our societies" to attack workers' discontent and alienation at its roots since, otherwise, those rebellions can threaten the whole survival of the Western economic system—a euphemistic term which is used to define Western capitalism. The representatives of the bourgeoisie or capitalist class, or, to use a more American term, the corporate class, as the most class-conscious of all classes, tend to perceive quite clearly from where they sit where trouble may come from, i e, from the working class rebellion against the main column on which the entire capitalist system is built: the nature and the conditions on which basis work is extracted from the workers [2].

On the other side of the ideological fence, progressive forces in the United States have only recently begun seeing signs of that potential storm. Many, however, still seem to be stuck in that scenario so widely emphasised by ideologists of capitalism and radicals alike that the working class has practically disappeared as agents of change, and, instead, has been absorbed into society, becoming part of the larger consuming and undifferentiated masses. According to some radical theorists, other groups are supposed to have taken over that task of carrying on the much needed struggle for change. The working class, however, has been 'lost', and has become part of that one-dimensional society [3]. Witness, for example, a most recent publication edited by a leading radical in this country who, in covering the changes in the cultural meaning of medicine, refers in his introduction to the impact of blacks' and women's struggles in the redefinition of health and medicine, but not once does he refer to the struggles which are taking place at the sites of work in the Western capitalist societies [4], struggles which I believe are among the most important ones in changing the nature of our society, including the definition of health and medicine. Just in the United States alone, millions of workers were involved in strikes last year which had to do primarily with work conditions and health. From the wildcat strikes among steelworkers in Ohio who asked to change conditions of work and medical regulations which applied in their working places, to the coal miners who struck for three months—threatening, as President Carter indicated, the stablity of the economy, i e, US capitalism—for the right to strike for health and safety conditions and for the right to retain some form of control over their health plans, many instances show that major struggles are taking place at the work place questioning the meaning of work under capitalism and its effects on the health and well being of our working populations. Health-related issues have been triggering points in many of those struggles, and health-related movements have had an important impact on changing the nature of political and social institutions, including labour's own institutions. A most recent example is the key role played by the Black Lung movement in creating Miners for Democracy. That movement rallied the majority of coal miners around the issue of democratising their union, the Union Mine Workers, and overthrowing the corrupt leadership of Boyle [5]. A very important issue—a key one—in that fight was a health related issue, i e, the need to recognise and compensate black lung as an occupation related condition, and the right to strike for safety conditions. The miners fought a tough battle to redefine health and medicine, showing—against the verdict of coal companies, state and federal legislative bodies and agencies, and even large sectors of the academic community—that coal mining was indeed a very unhealthy occupation in our society.

The history of the working class in the United States, and other countries as well, is punctuated by a continuous struggle to redefine the nature of work and health. And these struggles have heightened to such an extent that, as the Trilateral Commission indicates, they are threatening the cur-

rent international capitalist order.

In summary the fight for the realisation of health is very much at the center of the conflict between capital and labour which takes place at the work place and heightens in moments of crisis like the current one. The struggle which occurs at the places of work in our Western societies is a most important one, since it questions the very basic social power relations of capitalism [6].

Nature of Work under Capitalism

Let us analyse the conditions of work of the working class, that class by whose sweat and pain the goods and services in our society are produced. A primary characteristic of work is that its controllers increasingly shape the nature of work to optimize their pattern of control over (1) the productive process; (2) the individual producers; and (3) the collectivity of producers—the working class [7]. By means of this process, the workers are: (a) compartmentalised into increasingly narrower tasks; (b) hierarchicalised by a division of labour which reproduces the class relations in society; and (c) expropriated from all possibility of controlling, influencing or having a say in the design or development of the work process of the products they create.

The outcome of this process is a set of relations which cannot be defined as less than totalitarian. Democracy, the capacity of individuals to control their own lives, stops at the gates of the working places. This set of authoritarian relations where one class—the bourgeoisie—controls that process of production and work, and the other—the working class—doesn't, is what Marx called the *dictatorship the bourgeoisie,* understanding as such not a specific political form of government but rather an overwhelming dominance and control which the bourgeoisie has over the means and process of production. Nowhere for the millions of workers does that dictatorship appear more clearly than at the place of work. Michael Bosque, in his usual vivid way, puts this quite clearly when he invites the reader to

> Try putting 13 little pins in 13 little holes 60 times an hour, eight hours a day. Spot-weld 67 steel plates an hour, then find yourself one day facing a new assembly-line needing 110 an hour. Fit 100 coils to 100 cars every hour, tighten seven bolts three times a minute. Do your work in noise 'at the safety limit', in a fine mist of oil, solvent and metal dust. Negotiate for the right to take a piss—or relieve yourself furtively behind a big press so that you don't break the rhythm and lose your bonus. Speed up to gain the time to blow your nose or get a bit of grit out of your eye. Bolt your sandwich sitting in a pool of grease because the canteen is 10 minutes away and you've only got 40 for your lunch-break. As you cross the factory threshold, lose the freedom of opinion, the freedom of speech, the right to meet and associate supposedly guaranteed under the constitution. Obey without arguing, suffer punishment without the right of appeal, get the worst jobs if the manager doesn't like your face. Try being an assemble-line worker [8].

But these characteristics of assembly line work are not unique to workers in the automobile industry or workers in manufacturing alone. Many other studies have been done showing how assembly line work where the individual worker is carrying out *predetermined tasks* over which he or she does not have much control, is also the most frequent type of work among sales, clerical and large sectors of public service workers. Indeed, that expansion of the atomised hierarchical and authoritarian division of labour growing rather than diminishing in most areas of work in society, and is being presented as needed to increase the efficiency and productivity of the workers, i e, to extract as much work as possible from the worker. But that demand by representatives of the capitalist class is not made without misgiving about how long the working class will tolerate those conditions of work. As a leading exponent of the establishment put it, "How long can our political system stand the seventy million who live the majority of their working hours in an atmosphere which is totalitarian?"[9]

In the following pages of this article, I will explain how bourgeois ideology [by ideology, I mean, with Gramsci, the ethical, juridical, political, esthetical, and philosophical ideas about social reality as well as the set of customs, practices and behaviours which consciously or unconsciously reflect that version of reality] reproduces these dominant/dominated relations in the sphere of production (Section I); in the area of politics (Section II); and in the area of science (including medicine) (Section III). Needless to say, dominance does not mean complete control [10]. The working class does not remain passive against that domination. A *continuous process of class struggle* takes places where the working class also wins most significant victories and determines changes in the boundaries, means and instruments of that dominance [11]. How this class struggle affects that dominance in the world of production, of politics, and of science is also covered in Sections I, II, and III, respectively. In all three sections, *I have chosen medicine and medical knowledge as the primary points of reference.*

I

Work, Market Ideology, and the Reproduction of Power Relations

How is class dominance being reproduced? By different means. For example, the division of labour within the working class, by dividing the labour force into different categories, erodes a sense of class solidarity. Also, tending to reproduce those dominant/dominated relations are the conditions of work, highly hierarchical and authoritarian, which tend to create a habit of submission and subordination, further accentuated by a fear of unemployment or dismissal which tends to produce an obedient body of workers and citizens.

But besides these reasons, there are two others which explain the reproduction of these relations. One, very impotant ideologically, is that this type of work is presented, not as a result of specific power relations in soceity, but rather as a logical, rational, and natural outcome of the unavoidable and unchangeable industrialisation and technologisation of the work process. Thus, the culprit of workers' pains is seen in the unchangeable industrialisation and technology of work rather than in the social power relations which determine this specific type of oppressive industrialisation and technology. Needless to say, the absence in the current historical period of models of alternative processes of production and work strengthens the ideology that ours is the only logical, rational and natural way of organising production. But dominant

ideology tries to impress on the worker that those relations are not only *natural* but also *fair*. This dominant/dominated relationship in the world of production appears as a fair exchange in the labour market in which these exploitative relations are veiled and mystified by making them appear as a matter of free, unfettered and equal exchange between the labourer who sells his labour and the capitalist who pays a wage for it. Needless to say, bourgeois ideology may even be willing to admit and accept that much work today is oppressive and does not offer the possibility for self-fulfilment to the worker. But this same ideology will quickly add that the worker is compensated with a fair wage and that fair wage will allow the worker to obtain the key to the door to his self-fulfillment in the house of consumption. The worker, denied the possibility for creativity and self-fulfillment in the world of production, is said to be given that possibility in the world of consumption. Moreover, while he has no control over the work process, he is being told that he has control over the product of that process where, not as a worker but as a consumer, he can, through the free expression of his wants in the market, allocate the resources in that society. Thus the sovereignty denied to the worker in the world of production appears as the sovereignty of the consumer in the world of consumption. In this scenario, the criteria and discussion of fairness is not over the control of the process of work but, rather, on the price to pay and compensate the worker for his work so that he may reach a sense of fulfilment, control, and pusuit of happiness in the world of consumption.

Suffice it to say, it is of paramount importance for the reproduction of the capitalist system that all struggles at the point of production be shifted to the area of consumption, *with the focus of the struggle being the cost of labour—personal and social wages—rather than the control of the process of production.* The acceptance of this shift in the struggle from the world of production to the world of consumption by the trade unions and their consequent focus on the price of labour has been a primary reason for the reproduction of capitalist relations. As Gramsci indicated "trade unionism by organising workers not as producers but as wage earners had accepted and submitted to the rationale of the capitalist system where workers are merely sellers of their labour power" [12]. The shift from workers to wage earners is a key mechanism of reproduction of capitalist relations and responds to the intrinsic need of capitalism to separate the world of consumption from the world of production, focusing all areas of conflict on the former and not on the latter. Capital, in its position within the class struggle, clearly perceives the correctness of Marx's position when he wrote in the *Grundisse* that, ". . .the important point to be emphasised here is that whether production and consumption are considered as activities of one or separate individuals, they appear as aspects of one process in which production forms the starting point and therefore the predominant factor. . ." [13]. A predominant factor whose control capital cannot allow to be questioned.

A consequence of that bourgeois ideological dominance and acceptance of the *unalterability* of the process of work (and shift of the struggle from the world of production to the area of consumption) has been the acceptance by the unions of damage created at the work place as being unavoidable, and thus the *champ de bataille* has been on the compensation for that damage. Consequently, occupational medicine, a branch of forensic medicine in its beginnings, had, as its initial task, to define for management the nature and size of the damage which needed to be compensated. Occupational doctors, still called company doctors in many countries today, had as a primary function, to defend management interests and obfuscate or veil the actual damage created at the work place. The struggle was, and still continues to be, between labour which demanded a higher compensation, and capital (helped by occupational doctors) who wanted to minimise that compensation, denying for as long as they could that there was any relationship between work, disease, and death. Let me add here that not only occupational physicians directly employed by management, but many in academe, medical schools and schools of public health, supported directly and indirectly by grants or funds from industry or industry financed foundations, contributed to veil and mystify that relationship between work and disease [14].

A further consequence of the separation between the worlds of production and of consumption was that the damage created at the work place, when and if recognised, was perceived to be unrelated to the damage produced outside the work context. Thus, a dichotomy was established between the branches of medicine responsible for the definition and administration of disease at the work place (occupational medicine) and at the non-work place, in the world of consumption (medical care). That dichotomy, production/consumption, is till present today and is being reproduced in the structure of health services with different administrations responsible for those two separated branches of medicine.

In summary, that shift of the struggle around the work place from (1) control of work to compensation for damage; and (2) from the world of production to the world of consumption, has led to the establishement of occupational medicine as a separate branch of medicine historically controlled by management in charge of defining damage and compensation. Needless to say, the priorities within the social system were higher for the medicine of consumption than for the medicine of production, particularly considering that a primary function for the latter—the one of policing the labour force—was achieved under capitalism by other effective means than occupational medicine.

All these struggles on compensation were, for the most part, carried out under the supervision of the state institutions where capital was far more influential than labour, which leads me to discuss the second area where those dominant/dominated relations are being reproducd, i e, in the realm of the political institutions.

II

Work, Politicai Ideology and Reproduction of Power Relations

In the same way that it is of paramount importance for the reproduction of the dominant/dominated relations at work to shift all struggles around the control over the pro-

cess of production to world of consumption, it is equally important to shift those same struggles from the world of work to the world of representative politics. Indeed, just as the worker/subservient relationship is concealed at the economic level of our society under the ideology of consumer sovereignty, the worker/subservient situation is concealed at the political level with the dominated worker being presented as citizen/sovereign. According to bourgeois ideology, people decide through the market what they consume and through the political process what they want. A clear representative of this position is Eli Ginzberg, Professor in the Business School at Colombia University, who begins a book entitled *The Limits of Health Reform: The Search for Realism*, with the following sentence. "In our society, it is till the citizens who, through their voice in the market place and in the legislature, ultimately determine how their resources will be allocated" [15]. According to this ideology, workers become citizens, and as such, have the same rights as the controllers of their work. The assembly line workers are supposed to have the same rights as the controllers of their work. The assembly line workers are supposed to have the same political and juridical weight, according to legislative discourse, as the Henry Fords of America. Both categories—bosses and workers—are abstracted into a new category, the citizens who decide, with equal weight, the major political decisions. In the political - juridical realm, they are both equal. But is it really true that they both have the same power to choose, decide, and develop different political alternatives? Many studies have been written showing that the Henry Fords of America, or of any other Western capitalist country, have far more power—an overwhelming power to shape the nature of what is discussed, voted upon and presented in the political debate—than the assembly line or other type of workers[16].

In order to consider them with equal political power, Ginzberg and others with him have had to consider them as individual citizens, an abstract category which levels off everyone independent of their position in the world of production where goods and services are being produced. But men and women under capitalism are not equal. That assumed equality in the realm of politics is continually shown as inequality in the realm of production. Under capitalism, the relations of production allocate men and women into different social classes, defined by their differential access to and possession of the means of production[17]. Agents within those classes have, indeed, different political and thus juridical power. The class which owns, controls and possesses the means of work has a dominant hegemony in the political - juridical apparatuses of the state and in the ideological - cultural apparatus of society[18]. It goes without saying that the intellectual representatives of that class deny this, dismissing it as a simplification, tolerable for "ideologues" but not for reasonable people. They present it as a matter of fact that the political juridical institutions are an outcome of people's will who, via the electoral process in representative democracy, periodically elect those on whom authority is being bestowed. Consequently bourgeois dominance in the apparatus of representation is denied by burgeois ideology in which bourgeois domination is veiled and mystified as representing the popular sovereignty and the *vox populi*. According to this ideology, the workers, regardless of how exploited in the economic arena they may be, are still supposed to be free and equal citizens who, by their will, have chosen, and continue to choose, a system which reproduces that system of exploitation. This is the most important ideological legitimation of the bourgeois rule, i e, people want it and choose it.

It is worth stressing that in this scheme of things, democracy is not—as Lincoln said—government by the people—but one occasionally *approved* by the people. Democracy is thus defined differently from self-governance. In such a democracy, governments come and go at the approval of the people. In this respect, the government is assumed to represent *we, the people*, and what happens in our societies is what we, the citizens, want. As Etzione recently indicated in *The Washington Post*, "we, in the United States, have decided that we value production more than risk or damage at the work place"[19]. And that *we* is supposed to mean, of course, the American people who have expressed their political will through their political institutions. We, the citizens, have chosen to maximise production rather than safety at work. It speaks of the overwhelming dominance which the bourgeois position has in official and academic discourse, that those authors such as Ginzberg, Etzione and many others can consider these expressions as merely factual and absent of ideological meaning. They would strongly deny, of course, that they are bourgeois ideologists who reproduce the scheme convenient and favourable to dominance of our lives by the bourgeoisie. It is easy to predict that the bourgeois theorists would dismiss as 'rhetorical' the interpretation that it is not we, the American people, but the capitalist class which primarily—although not exclusively—dominates the state functions; and that it is not we, but the controllers of work, who decide on the nature of production and consumption in society. They would, indeed, dismiss that as Marxist "rhetoric". But they do not realize, or want to realize, that theirs is also a rhetoric and one which reproduces a pattern of class power relations where the minority and not the majority makes the major decisions. In summary, each ideological position has its own discourse dismissed as 'rhetoric' by its adversary. The untenability and incredibility of bourgeois rhetoric which assumes that we, the American people, decide on major issues in society, is increasingly clear for all to see. The majority of American citizens who belong to the working class and lower middle class know reality far better than the bourgeois theorists. In many polls, they have expressed their belief that the two major parties are controlled by corporate America and that the government institutions work principally for the benefit of Big Business—that folksy term used to refer to the capitalist class[20].

In summary, then the dominant/dominated relations at the work place are being reproduced by shifting struggles from the world of production to the world of representative politics where the bourgeoisie is the dominant force. It is of paramount importance for the bourgeois order that a clear separation be established between the *economic* class struggle confined within trade union battles (primarily concerned with the price of labour and compensation of work and damage), and the *political* struggle carried out primarily by

the political parties in the realm of representative democracy. As many points in history, from the General Strike in Britain in 1926 to the May events of France in 1968, show quite clearly, the shift of the place and focus of struggles from the place of work to the arena of representative politics has had a most important effect in diluting threats to the bourgeois order. But why this dilution—this weakening of that threat when the area of struggle shifts from the floor of the factory to the parliament? One reason is that representative democracy converts the process of participation *from active to passive*, delegating popular power to elected and/or selected representatives. These representatives, however well they may represent the interests of the working class and popular masses, have to conform to a set of rules and operate within a set of *state institutions where the bourgeois is, by definition, dominant*—a bourgeois dominance which gives its character to those institutions, including the institutions of representation and mediation[21]. Thus, it has always been in the interests of the bourgeoisie to demobilise the mass struggles occurring in the places of production by shifting those struggles to the parliament or its equivalent.

The previous paragraphs should not be understood as shying away from or slowing down the struggles which need to be carried out within the state and organs of representative democracy. *The class struggle carried out within the apparatuses of the state can lead to substantial victories for the working class.* The National Health Service in the United Kingdom, for example, was, no doubt, a remarkable achievement for the British working class. But it would be wrong to consider the NHS as a socialist apparatus within a bourgeois state [22]. I have shown elsewhere how the NHS is under the hegemony of the bourgeoisie, a hegemony which appears in the ideology, composition and distribution of medicine in the UK [23]. Similarly, the occupational health legislation which has appeared in the United States from the late sixties and early seventies has to be seen also as a great achievement for the US labour movement. But the fact that these achievements have occurred within a state that is under bourgeois dominance explains the limitations and the nature of that progressive legislation. The consequences of bourgeois dominance are many. One is that programmes established by legislative mandates tend—*in the absence of continuous pressure from the working class*—to be manipulated by the components and strata of the bourgeoisie which are affected by that legislation. Lobbies of those groups are "always there, close to the corridors of power" to limit and change the progressive impact and nature of those programmes. But, more importantly, those programmes have to operate within parameters which are defined by the overall power relations in that society and which cannot be touched upon by those programmes. For example, great stress is made by all governments that occupational health programmes cannot interfere with the overall pattern of capital accumulation. Capital formation and the subsequent class power relations which it sustains cannot be affected by that type of legislation. And when it is, enormous pressures are brought to bear on governments to assure that that situation be reversed.

Last but certainly not least, another consequence of bourgeois dominance in the apparatuses of the state, including those progressive programmes, is that the implementation of those programmes is carried out within the ideological framework convenient to the reproduction of the bourgeois order. For example, the prevalent approach of state regulatory agencies in occupational medicine is to protect the worker against an environmental agent such as the toxic substance which can harm the worker. Consequently, a struggle takes place around the allowable exposure of the worker to that toxic substance [24]. This struggle *is a very important and needed one*. But it is still carried out within that ideological dichotomy of worker versus environment which assumes and independence and autonomy where the worker is on one side of the working scène and the environment is on the other. The dichotomy of patient or potential patient versus environment characterises, as I will discuss later on, the conception of risk and disease in bourgeois science. In the same degree that the bacteria was perceived to be the external cause of disease, the toxic substance is now perceived to be the cause of that disease. In either case, however, such a dichotomy is a faulty one. The social power relations which determine the environment of exposures also determines the nature of the work process and of the agents of that process, i e, the workers. The social power relations which determine the working environment also determine how the worker fits within that environment, relates to that environment, and perceives himself or herself in relation to fellow workers and to the controllers and managers of that environment. In other words, by focusing only on a specific item of that environment (the toxic substance) and by not touching on the power relations which shape both the environment and the worker, the bourgeois order is reproduced.

III

Bourgeois Dominance, Ideology and Knowledge in Medicine

In previous sections, I have discussed how bourgeois dominance appears in the world of production and in the political-juridical level of society, and how that dominance has many implications in medicine as well. In this section, I will focus on how that class dominance appears also in the production of knowledge in medicine. Many studies have been written showing how bourgeois dominance of our research institutions including medical research institutions has determined a set of priorities that, while presented as apolitical, are, in fact, clear political statements which reflect the class dominance of those institutions. Elsewhere, I have discussed how that overwhelming class dominance of our research institutions explains, for example, why most of cancer research in Western capitalist countries has focused on biological and individual behaviour, but not on other factors such as carcinogens that exist in people's work places which could be threatening to the sections of the bourgeoisie that have a major influence in the funding institutions for cancer research [25].

It would be erroneous, however, to believe that those cancer research priorities are merely a result of the influence of

powerful interest groups in the top corridors of power in funding agencies. There is more to it than that. These groups belong to a class—the bourgeoisie—which has an ideology or vision of reality with an internal logic and consistency which, in turn, leads to the support of some positions, conclusions, and priorities and to the exclusion of others. This bourgeois ideology is the dominant one under capitalism. That it is dominant, however, does not mean that that bourgeois ideology is the only ideology. In this regard, it has to be stressed that each social class had its own vision of reality and ideology. In other words, there is not under capitalism, just a single ideology which is upheld by all classes, races, and sexes. I stress this, because on both sides of the ideological spectrum, there are ideological currents which postulate that there is in any society *just one ideology*—the dominant or ruling ideology—which has resulted from that society's choice, wills and wants (as the bourgeois theorists believe), or from an overwhelming dominance, tantamount to control, which the bourgeoisie has in that society [26]. Agreeing with Marx, I believe that classes have different ideologies which also appear in different forms of culture.

> Upon the different forms of property, upon the social conditions of existence, rises an entire superstructure of distinct and peculiarly formed sentiments, illusions, modes of thought and views of life. The entire class creates and forms them through tradition and upbringing [27].

But one of them, the ideology of the dominant class is the dominant ideology. As Marx and Engels indicated

> . . .*the ideas of the ruling class* are in every epoch the ruling ideas, i e, the class which is the ruling *material* force of society, is at the same time its ruling intellectual force [28].

But this 'ruling' does not imply that the working class ideology is either non-existent or absorbed in the bourgeois one. Nor does it imply that a clear-cut division exists between the two ideologies with a well delineated boundary between them. Class struggle is continuously taking place with victories and defeats which influence both ideologies. For example, I have already indicated in previous pages how bourgeois values appear in the working class. An example is when the working class accepts the belief that the nature of work is determined by industrialisation. And vice versa, the rhetorical (although not actual) acceptance by the bourgeoisie of democracy as a part of dominant ideology was forced by the working class on the bourgeoisie, when the latter social class needed an alliance with the former in its struggle against the aristocracy, then hindering the rise to power of the bourgeoisie [29]. In other words, democracy was not a set of values and practices spontaneously created by the bourgeoisie, but, rather, an ideology forced on the bourgeois ideology by the working class. The bourgeoisie has always fought by all means the expansion of democracy, including the expansion of universal suffrage, freedom of association, freedom of the press and many other freedoms which the working class has had to win with great sacrifice and not without heroic struggle.

In summary, there is, under capitalism, a dominant ideology which appears in all institutions including the institutions of science and medicine.

Class dominance in scientific medicine

How does the bourgeois vision of reality appear in science and medicine? In many ways. Let us outline some of them.

Dichotomy of Science versus Ideology

An extremely important view within bourgeois ideology is that there is a clear-cut dichotomy between science and ideology. Actually, science was the creation of the nascent bourgeoisie and was contraposed to religion (seen as the ideological expression of aristocratic dominance) which it was considered to transcend and supersede. Science was supposed to be a new global vision of reality which would rationalise and legitimise the new bourgeois social system. Galileo, one of the founders of the scientific revolution—and who, incidentally, was working as an advisor to coal owners on how to increase the rate of exploitation of coal miners [30]—established the basis for the creation of new knowledge based on what was called objective observation and not on theology. And that dichotomy, objectivity versus subjectivity, science versus ideology, has lasted throughout the history of science. Science was thus perceived as a body of neutral and value free knowledge built in a painstaking and linear process in which each new scientific dscovery was built upon a previous one. Science and technology became part of the forces of production and as such, their development was considered to be intrinsically positive. According to bourgeois ideology, science and technology (and the process of industrialisation which they determine) were forces of progress, determining, almost in a fatalistic way, the nature and shape of society. The most recent versions of those positions are the ones taken by Daniel Bell [31] and others, who indicate that power has shifted from the owners of the means of production to the managers of the process of that production and, more recently, to the producers—the scientists—of what is perceived as the most important ingredient of production, i e, science and technology.

It is worth stressing here that the bourgeois interpretation of the value free character of science has also appeared within the labour movement, particularly since Stalin [32]. As Sweezy and Bettelheim [33] as well as Lecourt [34] have eloquently indicated, the forces of production, including science and technology, under Stalinism were perceived as neutral. Their development was perceived to be a primary condition for the achievement of a change in the relations of production at a later stage. That change in the relations of production was perceived as needed, because they were retarding and hindering the full development of the forces of production. [Social relations of production are the relations which exist in a given process of production between the owners of the means of production and the producers, a relation which depends on the type of ownership, possession, capacity for allocating and designing those means of production and the use of the products of that process of production. Forces of production are the forces, instruments, labour and knowledge which are organised to produce goods and services in any society. How the forces of production are organised, designed and related among themselves is deter-

mined by the social relations of production.] In this dichotomy—forces versus relations of production—the forces of production were primarily understood as the instruments of production, and their development was considered to be the primary motor of history. The point that has to be stressed here, and Lecourt ignores it, is that instrumentalist understanding of forces of production already appeared in Lenin. It was Lenin who believed that the Western forces of production (including Taylorism) should be imported and put to proper and better use by the Soviet revolution. Lenin was an enthusiast of Taylorism. As Claudin-Urondo has indicated, Lenin conceived science and technology as neutral entities, rather like tools, the function of which can be changed depending on the use being made of them [35]. It should be pointed out that immediately after the October Revolution, a massive democratisation in scientific institutions, such as in the medical ones, took place with changes in the pattern of class control of medical schools and other scientific institutions and with changes in the class origins of the medical profession and other scientists. These changes had quite an impact in redefining the nature of those institutions, and in redefining the process of creating scientific knowledge. That democratisation had a very significant impact in redefining the nature of both scientific institutions and science itself.

The priorities within medicine, for example, changed quite substantially, and initial changes in the understanding of medical knowledge started taking place. This process of democratisation, however, was strongly reversed later on, in particular under the Stalin regime. Class control of scientific institutions and class origin of the scientists were reversed most dramatically under Stalin, giving strong political weight to the experts (scientists and technocrats) who became the controllers and administrators of scientific knowledge, closely supervised by the party apparatus. In this scheme of things, the development of the USSR meant primarily the fantastic growth of the forces of production (including science and technology) and the better redistribution of the product of that process. But it did not change the process of production and work nor those forces of production. The nature of science and technology (and, as I have shown elsewhere, medicine) did not change under Stalinism [37].

Foces of production are not neutral, however. They carry with them the social relations of production which determine them. In other words, a factory or a hospital is not a neutral institution. It is a hearer of power relations which determine how work in the institution is done, by whom, and with what type of instruments. How the work process takes place in these and other institutions in society is determined by the power relations existent in that society. It is not the process and forces of production which determine the social division of labour (as the theorists of industrialism postulate), but, rather, it is the social division of labour, its concomitant power relations and the ideological relations which those power relations carry, which determine the forces of production including science and technology. The power relations in society appear also *within* scientific knowledge, and the bourgeois ideological dominance appears and is being reproduced in the production of knowledge itself. The dominant ideology reproduces itself in scientific knowledge. And this reproduction takes place, not only by selecting the subjects of inquiry, but also by choosing the method of inquiry, and the relations which the researcher or inquirer has within the overall process of production. Needless to say, this position—that bourgeois ideology reproduces itself in science and thus science is value loaded and not value free—is continuously denied by scientists and other bourgeois theoreticians. Science appears as the epitome of objectivity. And all series of ideologies rush to be called sciences to gain legitimacy and credibility in bourgeois society. Not only natural sciences, but a long list of ideological positions appear with the sanction of sciences, e g, business sciences, management sciences, social sciences, political sciences, economic sciences. Sciences become the newly accepted vision of reality which would enable the citizenry to cope with the world in a better fashion. All types of ideologies are thus made compulsory subjects in our scholarly institutions, from schools to academe, provided they are presented as sciences (i e, "value free and neutral"). In this way, while the parents of a ten-year old child would strongly object to having him/her subjected to compulsory classes of a certain religion or certain ideology, they would not object, or would not be given the right to object, if that subject were, or is, presented as a science, e g, economic science. Science becomes that magic word which allows the transformation of value loaded knowledge into a value free one. Thus, the dichotomy of science/ideology constitutes a most powerful ideology for the reproduction of bourgeois relations.

Division Between Experts and Laymen

Once this dichotomy of science/ideology is established, then we have to ask what is science? And the bourgeois response is that science is an objective body of value free, classless and universal knowledge, based on testable observations of reality. As such, the production and reproduction of scientific knowledge takes place place in scientific institutions by individuals who—in the overall social division of labour—have been assigned the task of producing and reproducing that knowledge, i e, the scientists. *Science then becomes what scientists—a small group of individuals in society—do. And scientific medicine is what medical scientists and practitioners do.* Needless to say, all systematic knowledge which is produced outside those institutions, and by individuals other than scientists, is not considered science. According to this criteria, the documents produced by research groups in occupational medicine that concluded in the thirties, forties, fifties and even sixties in the United States that there was not a relationship between black lung and coal mining were supposed to be "scientific documents and conclusions" and thus trustworthy. On the other hand, the knowledge accumulated by generations of coal miners—knowledge which appeared in their culture as folk songs, popular writings, etc—that the work in coal mines was destroying coal miners' lungs was dismissed as cultural, folksy, ideological and in summary untrustworthy. Thus, knowledge is legitimised only and exclusively when it comes from the scientists. This dichotomy of science/ideology then appears operationally as the dichotomy of expert/non-expert in which the control of the definition

of science and expertise is delegated by the dominant bourgeoisie to another class, the petit bourgeoisie or professionals who carry on that task, namely, the production of knowledge under the hegemony of bourgeois ideology.

This last point of delegation raises the question of the autonomy of science. Can science become autonomous from the dominant ideology? My answer is yes and no [37]. Yes, *in the limited sense* that once established, it has an internal logic of its own, i e, the logic of that discipline or branch of science. No, *in the major sense* that scientific knowledge is continuously growing under the dominance of bourgeois ideology. In other words, scientific knowledge and scientific situations are under bourgeois dominance, and that reality shapes the nature of that knowledge. For example, and as I will explain in the next section, bourgeois dominance in medicine established a vision and an understanding of disease in which that disease was seen as the lack of equilibrium within the different parts—organs and humors—of the body. This specific understanding of disease generated a medical knowledge which developed autonomously. But the division of labour within medicine—specialisation—developed according to the bourgeois understanding of disease. Consequently, this internal logic of scientific medicine led to the creation of specialities which follow organistic bases: cardiologists, nephrologists, etc. Thus, medical knowledge developed according to its internal logic given by that bourgeois conception of disease. In other worlds, *bourgeois dominance always determines in the ultimate instance what occurs in the realm of scientific knowledge*[38].

How Bourgeois Ideology Appears in Medical Knowledge

In the previous section, I indicated how the bourgeoisie's definition of science—knowledge produced by an elite, the scientists—appears and is reproduced in our society. In this section, I will discuss how that bourgeois ideological dominance over science appears in the production of knowledge. But, first, let us clarify what we mean by production of knowledge. It is the process whereby a perception of reality is transformed into a specific product, i e, knowledge, a transformation which in science takes place by intellectuals whose primary instruments of work are the theories and methods of science. Scientific theories in each science consist of a group of concepts which belong to that specific branch of science (e g, the law of gravity in physics). Scientific method is the way in which those concepts are used. Both theory, and method allow that intellectual—the scientist—to transform this perception into knowledge [39]. Needless to say, this knowledge is being reproduced, not in abstract but in specific institutions, subjected to class hegemony and by scientists whose very specific visions of reality are moulded by the ideology of the dominant class (the bourgeoisie); their own social class (the petit bourgeoisie); their race; their sex; their discipline; their political position, among others. The scientist does not leave all those ideologies outside the walls of the scientific institutions. The scientists carry those visions of reality in the production of knowledge as well. That production is submerged into and is part and parcel of those ideologies, of which the most important one is the ideology of the dominant class or bourgeoisie.

How does this bourgeois dominant ideology appear in medicine? By the submersion of that medical knowledge into the positivist and mechanistic ideology which typifies science created under the hegemony of the bourgeoisie, and which I would call bourgeois science. Actually, positivism and mechanism appeared as the main ideologies of the bourgeoise in the nineteenth and twentieth centuries in Europe with the works of Hume. Comte, and, later on, Durkheim. According to positivism, science must focus on specifics to build up the general, looking at social phenomena as if those phenomena were natural, ruled by natural and thus harmonious rules. As Durkheim indicated, positivism reduces social phenomena to natural phenomena [40]. And within that interpretation, causality was supposed to be explained by association of immediately observable phenomena.

Positivism appears in medicine in its definition of disease as a biological phenomenon caused by one or several factors which are always associated and observed in the existence of that disease. For example, in one of the most widely used textbooks on epidemiology in the Western world, MacMahon describes epidemiology—the science of studying the distribution of health and disease—as an extension of demography, and he defines that distribution according to age, sex, race, geography, etc, giving major importance to those individual characteristics which are either biological or physical. Moreover, in explaining causality, MacMahon quotes Hume and indicates that causality can only be seen but not explained, since we can only focus on the degree of associations between several subsequent events [41].

A legitimate question at this point is to ask how that positivist conception of medicine came about. To answer that question, we have to go to the origins of scientific medicine as we understand it today. And these origins appeared primarily in the nineteenth and twentieth centuries during the same time that science appeared as a recognised and legitimised area of endeavour. Those were times of large social upheavals and unrest in Europe. Capitalism was being established, changing from a mercantile system to an industrial one. Those changes had an overwhelming importance in defining the nature of medicine as well as that of health and disease. One version advanced by the working class and by the revolutionary elements of the bourgeoisie, such as Virchow, saw disease as a result of the oppressive nature of existent power relations of society, and thus saw the intervention in smashing (the revolutionary) or modifying (the reformist) those power relations. Epitomised by the dictum that medicine is a social science and politics is medicine in a large scale (Virchow), its best representative was Engels whose work on the conditions of the working class in England was a dramatic document showing the political nature of the definition and distribution of disease. His solution was written, with Marx, in the *Communist Manifesto*, with his call for revolutionary change, where the first steps included the actual democratisation of political, economical, and ideological spheres in society. This version

of medicine, however, did not prevail. The bourgeoisie, once it won its hegemony, supported another version of medicine that would not threaten the power relations in which it was dominant. The bourgeois social order was considered from then on as the natural order where its class rules would be veiled and presented as rules of nature. Accordingly, disease was not an outcome of specific power relations but rather a biological individual phenomenon where the cause of disease was the immediately observable factor, i e, the bacteria. In this redefintion, clinical medicine became the branch of scientific medicine to study the biological-individual phenomena and social medicine became that other branch of medicine which would study the distribution of disease as the aggregate of individual phenomena. Both branches shared the vision of disease as an alteration, a pathological change in the human body (perceived as a machine) caused by an outside agent (unicausality) or several agents (multicausality). This mechanistic vision of health and disease is still the prevalent and dominant interpretation of medicine. Witness a recent deifinition of health and disease in Dorland's Medical Dictionary in which health is defined as "a normal condition of body and mind, i e, with all the parts functioning normally"; and disease is defined as "a definite morbid process having a characteristic strain of symptoms—it may affect the whole body or any of its parts, and its etiology, pathology, and prognosis may be known or unknown" [42]. From this mechanistic understanding of health and disease, it follows that the division of labour (specialisation) in medical knowledge and practice has evolved around component parts of that body machine, i e, cardiology, neurology, etc.

A related point is that the mechanistic interpretation of medicine was built upon knowledge which had been generated previously (blood circulation by Harvey in 1628; microscope by Van Leeuwencheck in 1683, and others). But it would be erroneous to consider scientific medicine as a mere linear evolution starting with those previous discoveries. *These discoveries did not lead to or create scientific medicine.* Rather, it was the victory of the industrial bourgeoisie which established that positivist conception of science and of medicine. The fact that those previous discoveries were used and presented as the originators of scientific medicine was due to the change in the correlations of forces and subsequent victory of the bourgeoisie as the dominant class under industrial capitalism. In this respect, scientific medicine was not the linear growth of previous knowledge. Rather, and to use a Kuhnian term [43], a shift of paradigm took place, establishing a new paradigm which carried a new, a positivist, vision of disease which added to what had already been built. This point has to be repeated, because it is part of the bourgeois understanding of scientific knowledge that this knowledge evolves linearly with "new" discoveries based on previous ones, as if these discoveries were the bricks on which the scientific building was constructed [44]. According to this understanding, science and technology grow and determine the nature of power relations in our societies; and the history of humanity becomes divided into stages determined by the discovery of new technologies which shape the nature of that historical stage, e g, industrial revolution, nuclear age, etc. Science and technology thus appear as the "motor" of history. But, as Braverman [45] among others, has shown, the so-called "technological breakthroughs" were not the ones which established new social orders—rather, the reverse was the case, i e, a new correlation of forces used those *already known* technological breakthroughs which were, later on, presented as the actual cause of that change in the social order. But those breakthroughs or scientific and technological discoveries were used and put forward by new correlations of forces. The victory and subsequent hegemony of the bourgeosie, for example, was the one which stimulated science, including scientific medicine. It was this political reality which determined the advancement of the positivist and mechanistic conception of medicine, health, and disease. In other words, the power relations which existed under the bourgeois order were the ones which determined the form and nature of medicine. It led to a scientific inquiry where the aim of that inquiry was the discovery of the cause or micro-organism, and the instrument of that inquiry was the microscope. By focusing on the microcausality of disease, however, science ignored the analysis of the macrocausality, i e, the power relations in that society. Scientific inquiry in medicine developed into a search for the cause: bacteria, parasite, virus or, later on, the toxic substance. Consequently, the strategy of intervention was the eradication of what was supposed to be the cause of disease. Needless to say, that interpretation of disease and of medical intervention was supposed to be presented and perceived only and exclusively as scientific and certainly not political. The dichotomy of science vs ideology was made quite clear and explicit. The alternative explanation, i e, the assumed "cause" was a mere intervening factor and the actual cause of disease resided in the power relations of that society, was dismissed as political, anti-scientific and in some circles perceived also as needing "eradication". In a report of The Rockefeller Foundation on Health in Latin America, it was stressed that there was a great need "to eradicate disease in vast areas of rural South America, otherwise the virus of the tropics will soon attack the metropolis, a virus that can be biological or, even worse, *political*"[46]. A clear call for scientific eradication of undersirable ideological explanations! The limitations of this strategy of eradication based on the unicausal interpretation of disease led to the later strategy of control instead of eradication. But, most importantly, that unicausal explanation was, and is, increasingly abandoned by the multicausal explanation of disease. Disease was later on supposed to be determined by several causes, some of which included socio-economic causes. But these socio-economic variables were added to other causes as if they were independent variables, independent of each other. Social class thus appears as one more variable which may be indirectly associated with the direct and most important explanatory variables. But this limitation of the concept of causality to the immediately observable association between disease (e g, cancer) and other specific events such as smoking, occupation and others is intrinsically limited since it leaves the key question unexplained, i e, how those different events are related. As a recent report on cancer research published by the United States government indicates, "a major defect in most cancer

research in the Western world (and I would add other worlds as well) is that most cancer research has been based on looking for a single or multiple cause, ignoring the interrelations among those assumed causes"[47]. What this report touches on is that the primary cause for our ignorance of the causality of cancer has been a limited understanding of causality, a limitation that comes from the positivist understanding of knowledge which I have indicated. By focusing on statistical association, positivists are touching on the appearance but not on the reality of the phenomena. In other words, what are presented as "causes" are not the actual causes [48]. The epistemological problem thus created cannot be solved either by indicating that those assumed causes are intermediate causes, part of a network of causalities whose linkage among the knots (intermediate variables) can be measured by statistical associations. The actual way of studying disease in any society is by analysing its historical presence within the political, economic, and ideological power relations in that specific social formation. And by this, I do not mean the analysis of the natural history of disease but rather the political, economic, and ideological determinants of that disease, determinants resulting from the overall power relations which are primarily based on the social relations of production. These power relations are the ones which determine the nature and definition of disease, medical knowledge, and medical practice. The understanding of the evolution and causality of black lung in the United States, for example, cannot come from an analysis of the natural history of black lung. It has to come from an understanding of the class power relations in the United States and how the class struggle shaped both the scientific definition, recognition, and knowledge of black lung in the United States and the actual production and distribution of that disease.

What I have said so far should not lead, however, to the opposite conclusion that the inquiry should be limited to the discovery of associations between specific power relations and disease. In other words, it is not enough to establish an association between specific forms of capital accumulation or, say, economic cycles and certain diseases. It is not enough to say that capitalism, for example, determines a certain disease profile. It is necessary to research how those power relations appear, how they are being reproduced, and how they determine the nature of death and disease in society. The different categories of analysis such as world of production, consumption, and legitimation need to be understood in detail and related to the specific mediating mechanisms that those sets of relations have with the apparent "causes" of disease. In other words, what is needed is not the incorporation of the social as mere additions to 'environmental' variables which act on the individual; but, rather, what is need is an understanding of how diseases mediate social relations, i e, how the social power relations determine both the social and physical environment and the individual's experiences within that environment, including disease. Actually, there is an urgent need to break with that new dichotomy of individual/environment which is as false as the old dichotomy of mind/body.

Consequently, the terms of the discourse have to be changed. Instead of using the dichotomy, individual/environment, we should analyse how social power relations determine disease. Taking black lung as an example, we have to understand how the social power relations defined and determined the working and living conditions of the coal miners; how the workers struggled against them; and how, in that context medical knowledge and medical practice came into being to obfuscate or clarify the nature of the damage inflicted on the coal miners. Needless to say, in the process of this struggle, individuals and classes have different knowledge, perception, and ideologies regarding their own experiences, which leads me to the last point I want to stress, namely, the existence of bourgeois science and working class science.

Bourgeois Science or Working Class Science: Utopia or Reality?

Knowledge is accumulated, stored, produced, and reproduced in the daily practice of people's lives. And the nature of that knowledge varies considerably, depending on the social class practices. Each social class has its own practice which appears in its own ideology and culture, i e. a vision of reality; and vice versa, that ideology and culture also appear as class practices. Thus, there is a bourgeois ideology, culture, and knowledge given and reflected in bourgeois practice. And there is a bourgeois knowledge and a working class knowledge. Both classes have different practices which generate different types of knowledge. The knowledge (legitimised under the name of science) produced by the bourgeoisie and reproduced in scientific institutions, which denied, for example, that there was any relationship between work and cancer, was bourgeois knowledge aimed at reproducing bourgeois power and practices. The knowledge (perceived in scientific discourse as 'hot air', 'folklore', or populist culture) produced by the working class and reproduced in its cultural forms, affirming that work was killing them, was, and is, working class knowledge based on experience. From this, I conclude that there can be two types of sciences: a bourgeois science and a working class science, each one based on different sets of knowledge and practice. To deny the above dichotomy is to assume a classless nature of knowledge, and thus a knowledge absent of practice. These two different and even conflicting visions of reality, the bourgeois and the working class visions, are not separated by clear-cut boundaries without one influencing the other. Through the process of class struggle, the working class develops and imposes its own vision of reality on bourgeois science: witness current interest in researching the relationship between work and cancer. This new development is due to a large degree to working class and the general population's outcry on the damage being created at the work place But, still, the hegemony which the bourgeoisie has in all scientific institutions explains the nature and bias of that response, a bias reflected both in the choice of areas to be researched and the means and ways of researching it. The scientist does his/her job in institutions *with* the bourgeoisie. In this respect, the scientist is, to use a Gramscian term, an organic intellectual of the bourgeoisie who explains the reality with and for the bourgeoisie. This relationship of scientist/bourgeoisie is overwhelmingly clear in the United

States where most research is sponsored either by private foundations or by the state where capital's representatives are extremely powerful and influential.

The alternative, the socialist alternative, would be to carry on scientific inquiry *with* the working class, analysing reality based on the extremely powerful knowledge given by the daily practice of the working class, and *under* the direction of the working class.

In this I see a great area of struggle: to democratise the institutions and to change the patterns of accountability of intellectual workers: and to work together with manual workers until eventually that dichotomy of intellectual/manual will be questioned and diluted. No doubt, this change of accountability requires a tough struggle: the one of democratising our institutions. In this respect, it was a great victory for the Italian working class when it won the right to control occupational health services at the factory level and also when it won the right to undertake research at the factory with the researchers chosen by the workers. This is a clear example of how the struggle for democracy and for knowledge are one and the same.

Let me finish by saying that I am aware that many eyebrows will be raised when reading this section of my article. The nightmare of the Stalinist distinction between bourgeois science and proletarian science will undoubtedly be remembered. And the case of Lysenko will be immediately raised as a warning against those dichotomies. My answer to that legitimate concern is that the Stalinist version of proletarian science was not the science developed by the working class (which was not in power), but rather the version given by the Stalinist leadership of the party which identified proletarian science with dialectical materialism as defined and controlled by them. The fact that the agency of control was mislabelled proletarian science did not make that science proletarian, nor does it make the whole concept of class bound knowledge meaningless. That is the mistake of Lecourt [49]. It throws the baby out with the bathwater. There is proletarian knowledge and mass knowledge which will fully appear and will flourish unhindered when there will be mass democratisation in the process of the creation of knowledge with the deprofessionalisation of science, changing not only the class composition of scientists but, most importantly, the method and creation of knowledge, knowledge created not by the few—the scientists—but by the many—the working class and popular masses. As Gramsci once indicated, while all human beings are capable of being intellectuals, only a few are assigned that task. Similarly, while all human beings are capable of creating knowledge, only a few are given that task. Mass democratisation would imply a redefinition and redirection of that process of the creation of knowledge. *This process would not mean, of course, the absence of a division of labour. But it would mean a change in the power relations in the creation of knowledge with a dramatic expansion of the capability of creation of knowledge, with the working class and popular masses being the agents and not the objects of that knowledge.*

In other words, science is a social relation and, as such, the key operational issue is not only *for* what class that knowledge is being produced (the uses of science) but, most importantly, *by* what class and its related question, *with* what class (the class character of sciences) that knowledge is being produced. The failure to understand the importance of these points explains the overabundance of references in which authors continue to search for the perfect socialist scientific method that would enable them to find the socialist truth. That search is not only a theoretical but a practical task as well. *And it requires a political and professional commitment to the working class.* In other words, it requires to break with the role to which the scientist is assigned under bourgeois order and to ally himself/herself with the working class, not to lead that class but to assist it in its potential for human liberation and creation of knowledge. Let me try to be very specific and advance an example of the proposed relationship with which I have experience, namely, two different ways and approaches to find reality at the work place.

One would be the bourgeois or positivist approach to find the nature of a specific health problem (e g, toxic exposures) in a factory and a way of solving it. The 'expert' (epidemiologist or any other social scientist) usually called by management would (1) establish a *hypothesis de travaille* based on his previous knowledge of that problem. Needless to say, it is part of the scientific ideology that he should be "objective" and unemotional about the issue under study. His only aim is to find the truth. As such, he would have a "healthy skepticism" about any subjective statements or situations, relying more comfortably on facts, and very much in particular on quantifiable facts: (2) try to obtain as much information as possible from each individual worker in order to ascertain the facts. Through questionnaires, interviews, medical records, etc, he would try to obtain from each worker as much 'objective' and quantifiable information as he could get and find relevant. He would also try to locate the collective dimensions of the problems by adding up the individual problems; (3) last but not least, he would try to test the hypothesis by statistical manipulation of quantifiable (objective) information.

He would finally submit a report to management's implementation. In that *modus operandi* of research, workers appear as passive subjects of research remaining in the background and not in the forefront in the analysis and solution of the problem. This method of inquiry and data gathering is the most frequent tool used in social science research. The citizens, workers, blacks, women, etc, are studied individually, providing information through key instruments of inquiry, questionnaires or interviews. In all these approaches, three ideological positions—presented as scientific conditions—are that (1) theory and fact are two separate entities of which the former is supposed to be built upon the analysis of the latter; (2) the expert, the holder of proper methods of inquiry, is the active agent while the studied object the worker or citizen is a passive one, i e, the mere provider of information; and (3) collective information is the aggregate of individual information. The process and findings of this scientific inquiry are, of course, presented as objective and value-free (universal and classless) [50].

It is not surprising that in the late sixties, when many anti-authoritarian movements appeared in the Western capitalist world, many of those analysed passive objects—workers,

blacks, women—rebelled against that science and against those scientists. At that time, alternative relations of production of knowledge were established. In many Italian and Spanish factories, for example, workers committees and assemblies were established which rebelled against the type of science that was carried out in those factories. From then on, they did not allow any scientists to come inside the factory and ask them questions [51]. Instead, they developed another approach in which the process of inquiry was carried out under their direction. Consequently, a new production of knowledge took place in which (1) all information regarding the specific health problem was (and is) produced and discussed collectively with the correct understanding that a collective problematic is far more than the mere aggregate of individual problematics. Moreover, workers assemblies have a collective memory and experience that puts their perspective. They know what is going on and what has been going on in that factory process and environment for a long time. And they have first-hand experience with what that problem has meant in their collective and individual health and well-being. Out of their collective discussion, they develop a hypothesis of what is happening in the factory regarding the specific health problem. In that process of generating and collecting data, subjective feelings, anxieties and uneasiness are the propelling forces which guide all processes of gathering both objective and subjective data; (2) the workers call in scientists of their own choosing to assist them in the collection and analysis of whatever data the workers feel needs study. In this process, the workers keep a healthy skepticism about the meaning of science, expertise, and objective information. They scrutinise all objective data, and through the process of mutual validation, they accept the value of the data depending on how it fits within their own perception of reality. It is worth stressing here that many years of exposure to occupational medicine has taught workers the lesson that science is not value free knowledge but very value loaded knowledge, reflecting the values of institutions where science is created and the values of scientists who create that science; (3) once agreed collectively on the nature of the problem, the workers demand to participate collectively in the solution of that problem.

This collective production of knowledge based on collective practice is an alternate form of production of knowledge to the individual production of knowledge, characteristic of the bourgeois model. Needless to say, it puts the scientist in a *different social relation with the subject of study.* It puts him/her in an assistant role with his/her information and knowledge being just a part of a broader and more important knowledge which is created by the practice of the working class. Needless to say, the majority of scientists would oppose that diminution of their protagonism, since it would diminish their power. Many arguments are likely to be used against that change of power relations—ideological arguments presented as scientific arguments to defend specific class interests. The bourgeoisie and the majority of profesionals will oppose that change by every means possible, including sabotage. Still, that the majority of professionals would oppose change does not mean, of course, that a minority within those professions cannot play a very important role in taking sides with the forces for change. But in that process of changing class alliances, they will have to change, not only their roles (from leaders to assistants) but also their methods of work and the social and political context in which they use them. And it will be in that new realm of practice that new social relations and a new science will be created.

Struggle for Democracy

I have shown in the three sections of this article how bourgeois ideological dominance reproduces dominant/dominated relations in the spheres of production, politics and science, including medicine. Also, I have shown how the working class rebels against this bourgeois domination in a continuous process of class struggle, which leaves its mark on all those spheres. The class struggle takes many different forms, but aims at changing and/or breaking with those patterns of domination which oppress the working class and popular masses. It follows, from what has been said, that their liberation requires the breaking of that pattern of control where the few and not the many decide on the nature of our societies. And, by democratisation, I do not mean the mere existence of a plurality of parties and existence of civil rights. I mean far more than that, I mean a profound change in the pattern of control of the spheres of production, consumption, representation, ideological discourse, and scientific endeavour where the many and not just the few control. Specifically, democracy cannot be seen as limited to the passive and indirect realm of representative politics. It has to be seen, as Marx and Engels said, as the massive, active and direct involvement by the collectivity of workers and citizens in the governance of social institutions where they work, reside, study, enjoy themselves and are being taken care of. As Hal Draper has indicated, the greatest contribution which Marx and Engels gave to the history of humanity was to reveal the clear symbiosis between socialism and democracy. As he put it, "Marx's socialism (communism) as a political programme may be most quickly defined, from the Marxist standpoint, as the complete democratisation of society, not merely of political forms" [52]. The struggle for democracy needs to combine struggles in the institutions of representative democracy, where power is delegated to full-time representatives—the "experts" in politics—with, most importantly, struggles to achieve forms of direct and mass democracy where power is retained by the users and workers in all societal institutions. For example, in order to change not only the priorities but also the nature of medical and scientific institutions, there is a need to win control of those institutions, not only indirectly through elected officials in the realm of representative democracy, but most importantly, through direct and assembly type of democracy where workers, employees, users and communities control those institutions. In other words, a socialist transformation will not occur without a massive and direct participation by the majority of the population in that process of transformation.

To sum up, there is a need for the working class, through its different instruments and forms of struggle, to aim at a massive democratisation of our societies, understanding democracy, not as an exercise in voting every so many years,

but, most importantly, as a direct form of participation on a daily basis by the working class and popular masses in all economic, political and social institutions (including the medical and scientific institutions). It is only in this way that the democratisation of our institutions will imply a massive transformation of the majority of our working populations from being passive subjects to active agents in the redefinition of those societies, a transformation that takes place as part and parcel of their becoming the agents and not the objects of history.

2. By 'Capitalism' I mean a mode of production in which a class, the capialist class, extracts as much labour power from each worker as possible; labour power that is needed to (1) put the means of production (owned, controlled and possessed by the capitalist class) to work; and (2) produce value, including profit. Labour power is the human energy and competence that the worker provides to enable the means of production to work. It is usually referred to as work.

20. Hart Poll. *Common Sense,* Vol 3, 1975. That lack of trust of American people in the US political institutions represents a major crisis of legitimacy of bourgeois ideology in today's US.
21. Contrary to bourgeois ideology that postulates that the state apparatuses are neutral and can be used undistinctively by any class or group, I believe that the state's apparatuses reflect the power relations of the whole of society and thus are under the dominant unfluence of the capitalist class. That dominance explains its composition (the class position of the top echelons of the state personnel), its structure and its function (i e, to reproduce the capitalist relations). For a further expansion of this position, see Part III, "State power and medicine" of Navarro V. *Medicine Under Capitalism.* Neale Watson, New York, 1978.
22. Two examples of that perception are Tudor Hart J. The point is to change it. *Med. in Soc.* 4, 1979, and Figlio K. Sinister medicine. *Rad. Sci. J,* 9, 47, 1979. Although different in their political position, they both share that vision of the NHS as a socialist island in the capitalist state. J.T.H. reduces socialism to a juridical-political category, i e, the nationalisation of the health sector. K F reduces socialism to the absence of market relations and to the mechanism of societal allocations done by the state for the "benefit of society". In that vision, socialism is defined by the relations of exchange, not by the relations of production. Socialism, however, is a social formation in which the working class and its allies are the dominant class. Thus, socialist control is working class control.

42. *Dorland Medical Dictionary,* Saunders, Philadelphia, PA, 1968.
43. Kuhn T. *The Structure of Scientific Revolutions,* Univ. of Chicago Press, Chicago, IL, 1962.
44. For a critique of the concept of linearity in scientific knowledge, see Kuhn T. *op cit.* Also for an alive but not always rigorous discussion on this subject, see Feyerabend P. *Science in a Free Society.* New Left Books, London, 1978. Neither Kuhn nor Feyerabend touch on the socio-economic and political determinants of the scientific breakthroughs, a key subject which leaves their positions wanting. A further fault of Feyerabend's work is the key determinant role that he considers scientists have in initiating or stopping changes. For example, in examining the situation of blacks, chicanos and American Indians, he writes that "much of the spiritual misery of the remnants of non-Western culture in the US is due to this uninformed intellectual fascism of most of our leading philosophers, scientists, philosophers of science. . ." (p 207). The roots of the problems, however, are much deeper than Feyerabend seems to realise. He does not touch for example, on the key issues of why those 'fascist' ideas are the ruling or leading ideas.

Economic and Political Weekly

A journal of current affairs, economics and other social sciences

Every week it brings you incisive and independent comments and reports on current problems plus a number of well-researched, scholarly articles on all aspects of social science including health and medicine, environment, science and technology, etc.

Some recent articles:

Mortality Toll of Cities—Emerging Pattern of Disease in Bombay: Radhika Ramsubban and Nigel Crook
Famine, Epidemics and Mortality in India—A Reappraisal of the Democraphic Crisis of 1976-78: Ronald Lardinois
Malnutrition of Rural Children and Sex Bias: Amartya Sen and Sunil Sengupta
Family Planning and the Emergency—An Unanticipated Consequence: Alaka M Basu
Ecological Crisis and Ecological Movements: A Bourgeois Deviation?: Ramachandra Guha
Environment Conflict and Public Interest Science: Vandana Shiva and J Bandhyopadhyay
Geography of Secular Change in Sex Ratio in 1981: Ilina Sen
Occupational Health Hazards at Indian Rare Earths Plant: T V Padmanabhan

Inland Subscription Rates

Institutions/Companies One year Rs 300, Two years 575, Three years Rs 850
Individuals Only Six months 125, One year Rs 225, Two years 425, Three years Rs 625
Concessional Rates (One year): Students Rs 125; Teachers and Researchers Rs 175

The 'Baby M' Court Case in the US

cindy jaquith

Some months back a New Jersey court gave a ruling on a surrogacy case which has sparked off intense debate in the west on the entire issue of surrogate motherhood. In the Baby M case, the child was taken away from the surrogate mother on the basis of a contract she had signed with the father of the child and his wife. A myriad of prejudices against women and working people—some falsely presented as feminist ideas—have been put forward, along with a generous dose of pseudoscience and mysticism both in the court and outside it.

THE New Jersey court case of "Baby M" reveals a brazen disregard for children. By taking the child away from her mother, Mary Beth Whitehead, and by upholding a 'surrogate mother' contract, Judge Harvey Sorkow has struck a blow against rights the working class has fought for more than a century and a half.

The case began when William and Elizabeth Stern went to a surrogacy agency to hire a woman to bear them a child. Agency head Noel Keane arranged a contract between William Stern and Mary Beth Whitehead. Whitehead signed papers agreeing to be artificially inseminated with Stern's sperm, carry a pregnancy to term, and then deliver her baby to the Sterns for $ 10,000 plus medical expenses. But in the course of pregnancy and the birth of the baby, in March 1986, Whitehead decided she wanted to keep her child, whom she named Sara. She informed the Serns and said they should keep their $ 10,000.

The Sterns filed a suit and immediately got Judge Sorkow to order Whitehead to hand her daughter over to the Sterns. The Sterns then went to Whitehead's house with five cops to seize five-week-old Sara. Whitehead escaped with the child to Florida, but private detectives hired by the Sterns tracked them down. The detectives took Sara away and turned her over to the Sterns, who renamed her Melissa.

Whitehead's Contract

Surrogate mother contracts are similar to involuntary servitude contracts in many respects, and just as exploitative, unjust, and invalid. The woman signs a contract guaranteeing that she will carry a pregnancy for someone else for nine months. According to Judge Sorkow's ruling, she is legally bound to this contract whether or not she changes her mind.

This is bad enough—but even worse given the nature of the rights she gives up. Whitehead relinquished control of her body for nine months with the contract she signed. She had to agree to "assume all risks" of the pregnancy, "including the risk of death." She had to agree to "abortion on demand of William Stern" if the fetus showed signs of "physiological abnormalities," determined by the doctor being paid by Stern.

Whitehead herself could not choose to have an abortion without "breaking" the contract. She also had to agree not to smoke, drink liquor, or use medications not prescribed by the Stern-paid doctor during her pregnancy. While these conditions were imposed on Whitehead, the contract allowed Stern to terminate the agreement immediately if Whitehead had a miscarriage in the first five months. And he wouldn't have to pay her a cent.

The other side of the contract that has no validity is that Whitehead agreed nine months beforehand to surrender a child she planned to bear. This is completely inhumane, both to the child and mother. Under adoption law, a woman has a period of time after her baby is born to decide if she wants to put the child up for adoption, even if she concluded at some point in her pregnancy that this is what she wanted to do.

Women's Right to Choose?

Gary Skoloff, the Sterns' lawyer, made the fantastic argument in court that surrogacy contracts are actually an advance for women's rights. "You prevent women from becoming surrogate mothers and deny them the freedom to decide... it's being unfairly paternalistic and its an insult to the female population of this country," he claimed.

This argument was defended by Jan Sutton, spokesperson of a group called National Association of Surrogate Mothers. "Surrogate child-bearing is not exploitation of women," she wrote in a letter to the *New York Times*. "It is our individual right voluntarily to create a child for another family. To deprive women of this right is clearly a threat to feminist concerns."

Surrogate contracts are not an extension of the fight for women's right to control their own bodies. That fight is to secure the right of the woman to decide when and if to have children, free from interference from the government, church officials, doctors, husbands, lovers, boyfriends, or any other individuals. This struggle has embodied the fight for birth control; sex education; safe, legal abortion; and protection from forced sterilisation. It is interconnected with the broader struggle by women to be treated equally with men in all aspects of society and not be disqualified because of pregnancy, children, or lack of children.

Surrogacy contracts run completely counter to this struggle, what it has already achieved, and the future it points to. Far from an expansion of women's rights, these contracts deny rights previously conquered by women and working people as a whole.

A *New York Times* magazine reporter visited the offices of Noel Keane. "His comfortable, two-story offices in Dearborn, Mich, were full of prospective surrogate mothers, often with husbands and babies in tow, and infertile couples who had come to check out the candidates for surrogacy," wrote reporter Annie Taylor Fleming.

"The well-groomed couples... were each assigned a private office, through which the surrogates were rotated, to proffer their fertility and show off the living, gurgling proof thereof." For each women and eventual baby he successfully markets, Keane pulls down $ 10,000 for himself.

Male companions of the women also get into the business. One man who accompanied his female friend to the office told Fleming, "I'll take care of her when she's pregnant again, but the baby means absolutely nothing. It's like watching someone's car for nine months. We're in it for the money; it's a business." Keane argues that he provides a public service,

that he is showing sensitivity to "the pain and cries" of the "infertile." Judge Sorkow upheld this notion of the 'rights' of the infertile. He ruled that state "refusal to enforce these surrogate contracts... wold constitue an unconstitutional interference with procreative liberty since it would prevent childless couples from obtaining the means to have families."

'Rights' of 'Infertile'

To believe Keane and Sorkow, a new class of oppressed people—'the infertile'—has arisen. No one should deny them their 'right' to 'their own' child, a 'right' supposedly guaranteed by the US Constitution.

But Keane and Sorkow have things turned upside down. The government has an obligation to guarantee that every child has protection and nurture—health care, education, and decent living conditions. This obligation extends to other dependent human beings as well, such as the aged and people who are incapacitated by physical or mental illness.

But the government has no obligation to guarantee every adult the 'right' to 'their own' child. Judge Sorkow claims the law should recognise surrogacy contracts in order to satisfy an 'Intense drive to procreate'. There is no instinctual drive to procreate, however. There is an instinct to have sex—procreation is sometimes a consequence.

The attitude that people must have 'their' child with 'their' genes so they can continue 'their bloodline' or 'family name' is deeply rooted in class society. William Stern presented this reactionary notion in the court case, explaining he had no living relatives because many were killed by the Nazis. He said he needed Whitehead's baby to continue 'his' bloodline.

The Nazis, of course, are the most famous advocates of continuing certain bloodlines. They also ended up trying to exterminate other bloodlines they deemed socially unfit.

Under capitalism, the welfare of the child is not the principal concern nor are the rights of the woman who gives birth. Defining the line of inheritance is. The working class, which has no property to pass on to its offspring, is nevertheless affected by ruling-class ideology about the family. Fears, insecurities, and hopes of immortality, all bred by class society, lead many working people to try to 'continue the family name'. This introduces enormous pressures, with the children being the greatest victims.

Surrogate mother contracts are simply the latest—and one of the most degrading—manifestations of the way capitalism treates children. If surrogacy served some socially useful purpose, it could be argued that society should promote its practice. But it serves no progressive purpose. Humanity is not on the brink of extinction. Many children are being born and many more will be. There is not a social need to increase the number of babies.

Surrogacy is not like adoption, which is socially necessary today. Despite the fact that adoption is immersed in profit-making and that abuses against the children and parents involved do occur, there is a need for this institution to help children without care.

And this is its starting point—not the 'need' of some adults to have 'their' child. The concept of adoption is that society must find a way to provide care to all children lacking it. That's progressive.

The concept of surrogacy is that society owes all adults the 'right' to 'their' child. There's nothing progressive at all about that—it is reactionary.

It opens the door to such things as the international baby racket that has received so much publicity and condemnation. According to the *New York Times*, the number of foreign-born babies adopted in the United States shot up from 4,868 in 1981 to 9,945 in 1986. The real number is undoubtedly much higher. Most come from Asia or Latin America. Some are outright stolen from their mothers by baby dealers; others are torn away under extreme duress by these merchants.

This happens because there are fewer children in this country available for adoption than there used to be, even though racist prejudices still prevent the adoption of many US-born children who are 'not white'. Capitalist businessmen preying on couples without children see a profit to be made, because the baby 'shortage' has driven the price of babies up.

But the fact that there are fewer homeless babies in the United States is good. It marks human progress on several fronts—in relation to society's treatment of children and other human beings, the advance of science and technology, and the advance of women's rights.

In many primitive societies, when it wasn't possible to feed everybody, it was the practice to kill some infants and other dependents. Under feudalism and lasting beyond, the first-born son in the families of the landed nobility had special rights over other children. This practice has also been wiped out.

The brutal exploitation of child labour in textile mills, coal mines, and agriculture has become illegal in this country. The labour movement won this victory, as it won the right to free, compulsory education through high school. A century ago, many children were still losing their parents in shipwrecks, epidemics, or other events. The number of human beings perishing under such circumstances is greatly reduced today in this country. And children without parents live under much better conditions.

Social attitudes toward 'orphans' and 'adopted children' have also been changing in a progressive direction. These children are less often seen as somehow abnormal and deserving different treatment than children who live with a biological parent. Prejudices have also subsided with regard to children born to unmarried women—so-called 'bastards' or illegitimate children.

Humanity as a whole has advanced and deepened its solidarity for all members of society. This has been the product of struggle by workers and farmers. And it is linked to advances in science and technology that have helped working people shed various aspects of exploitation, inequality, and prejudice.

Is Technology the Enemy?

It is important to recognise the progressive role science and technology play—including under capitalism. This is especially true in the light of arguments that surrogate births show society is becoming the victim of technology and predictions that science will turn most working-class women into 'breeders' of babies for the rich.

The trend is actually the opposite—women are having fewer children today than ever before and they have taken gaint steps away from their socially imposed role as 'breeders'. This has happened because of women's victories in the fight for abortion rights and birth control, changing attitudes toward women, changes in women's own self-perception, and science.

Scientific discoveries mean that women today are better informed about sex and health. Access to birth control and abortion, while still restricted to some degree, allows them far more decision-making power about when and if to have children. Technology has also produced labour-saving devices that have greatly reduced the hours women spend on domestic labour, further freeing them to participate in the labour force and society as a whole. Women have seized on these advances to struggle for and win greater rights.

One result of this is a decline in the number of children women have, now that they have more freedom to plan pregnancy or decide not to have children at all. According to the US Census Bureau, the average number of people per household was 2.67 in 1986, down from 3.14 in 1970. There is also greater social acceptance of couples who live together and decide not to have children, and of adults who choose to live alone, also a growing category, according to the Census Bureau.

One consequence is the 'shortage' of children to adopt. A new phenomenon has arisen in relation to this, that of couples frantically seeking 'their own' child, frequently after not having had children earlier in life. Prior to this, many children were adopted by relatives or neighbours who already had children and took in others as an elementary act of social responsibility.

Technology has helped make possible the current situation where there are fewer children to adopt. Technology has benefitted women and all working people—increasing life spans, lowering infant mortality, boosting food production, and reducing labour time. And as such, it is being used by the working class to lessen exploitation and reduce class, race, and sex inequalities. It is not technology that is responsible for abuses like surrogacy, it is capitalism, with its drive for profit and its warping of human values.

Surrogacy is and will remain a marginal practice. Far from being 'the wave of the future', it is actually a throwback to the past. Judge Sorkow's ruling upholding surrogacy contracts has simply opened up the debate about this practice, exposing its real nature to many working people for the first time. On April 10, the New Jersey Supreme Court overturned Sorkow's ban on visitation rights for Whitehead. She now has the right to see her daughter once a week for two hours.

Judge Harvey Sorkow, who presided over the New Jersey trial, called it a "routine custody case". His portrayal of the trial as a dispute between a "father" and a "mother" confused the issues and distracted attention from the exploitative and unjust nature of surrogacy contracts. A custody case usually arises when two people who have been jointly raising children separate and cannot agree on who will get the children. William Stern and Mary Beth Whitehead were never jointly raising Whitehead's newborn daughter and never intended to.

Stern's sole 'claim' to the child was a scrap of paper called a surrogacy contract. In upholding this 'contract', the judge argued that Stern is the 'biological father' of Whitehead's child. According to the judge, this gives Stern a 'right' to "his own biologically genetically related child". Whitehead was merely "the surrogate" hired by Stern to "carry his child to term".

Psychologist Lee Salk, a witness called by Stern's lawyers, went so far to propose that Whitehead be termed a "surrogate uterus" rather than a "surrogate mother", to remove any suggestion that she has a legitimate relationship to her daughter. But it is precisely Whitehead's biological, social, and emotional relationship to the child that is key to the case. Stern's supposed 'biological' connection is irrelevant. Stern is not the 'father' of Whitehead's child. Richard Whitehead, who is living with Mary Beth Whitehead and her other children, is the 'father' in this case. Being a 'father' is not determined biologically (leaving aside the fact that there is no scientific way to prove it was Stern's sperm that made Whitehead pregnant).

Throughout human history, a 'father' has been the husband or companion of a woman who is raising children. It is based on his relationship to the woman that a man becomes 'father' to the children. Due to death, divorce, or husbands who walk away, many women may then live with someone else, who then becomes a 'father' to her children. They remain 'fathers' as long as they are living with the woman and sharing responsibility for the children. In a growing number of cases, women are bringing up children without 'fathers' at all.

Being a sperm donor gives no man a right to raise the resulting child, any more than being an egg donor gives a woman that right. (In the practice called 'surrogate gestation', a woman is implanted with the fertilised egg of another woman. The 'surrogate gestator' carries the pregnancy and gives birth, turning the baby over to the other women. The practice is used in some cases by a couple of one race who hire a woman of another race to bear a child who will also "look like them".)

Neither eggs nor sperm can be the basis for deciding who is the 'mother' or 'father' of a child, or who has the right to bring that child up. It is the woman who carries the pregnancy, gives birth to the baby, and begins nurturing that baby who has the right and responsibility to raise the child—and the right to all the social benefits she needs to do so. The only reason the state should intervene to take her child away is if she is guilty of child abuse.

Nothing of the kind was proven in the case of Mary Beth Whitehead. The Sterns brought into court an army of psychologists and social workers who insisted Whitehead was an 'unfit mother'. Their evidene? Whitehead had a 'narcissistic personality disorder', in part because she dyed her hair; she gave her children pandas, instead of pots and pans, to play with; she had a shouting match with a nun who teaches her son at a Catholic school; she once worked as a dancer in a bar; and her husband was an alcoholic.

Lawyers also proudly pointed out that the Sterns make more than $ 90,000 a year, while Whitehead is dependent on the $ 28,000 her husband makes as a sanitation worker.

But none of this is relevant to whether Whitehead is 'unfit' to raise her child. What is relevant is that she gave birth to the child and began raising that child.

What are Society's Responsibilities?

In the struggle to end women's oppression and guarantee children the best care possible, the working class needs a twofold approach. It needs to fight for women's right to enter the work force and all arenas of society without any restrictions or discriminatory treatment because of their childbearing capacities. It also needs to fight for the government to carry out its responsibility to provide care for children and all other dependent human beings, instead of allowing the burden for this care to fall on individuals, especially on women.

The government should provide lowcost child care from infancy on up. It should guarantee an education, medical care, decent housing, and recreation for all the young, aimed at helping them develop into independent human beings. All laws or practices that discriminate against children—based on class, race, sex, handicaps, or 'legitimacy'—should be eliminated.

The working class must also challenge any disqualification of women based on their having or not having children.

This being with championing the right of women themselves to freely decide when and if to bear children. It means the right to safe, legal abortion and birth control, as well as sex education in the public schools. It means protection of women from forced sterilisation.

Women's physical ability to bear children should not be used as a pretext to super-exploit them on the job paying them less than men, excluding them from certain jobs, or denying them emoloyment if they are pregnant or already have children. The working class should demand equal pay for equal work and affirmative action so women can achieve full equality in employment and education.

Workers should demand full maternity benefits for women, including the right to return to the same job—without loss of accrued seniority time—after the birth of a child. Absence from work because of pregnancy should be treated exactly like other contractual situations related to leaves from work.

For women who have children, the working class should demand all the state aid they need to care for them. And it should defend their right to have the courts compel men who walk away from shared responsibility for children to pay child support.

The struggle for these demands is part of the fight for a different type of government, one that acts in the interests of workers and farmers, not a handful of capitalist families. By bringing such a government to power, working people will lay the basis for further measures to provide care for children and to achieve equality for women

(Continued from p 2)

puterised tomography nor nuclear imaging are tested in the same way as drugs are required to.

Not only instruments but many medical and surgical procedures are also introduced without adequate trails. For instance results of the systematic trial of amniocentesis were published only last year after its extensive use for over a decade. The chorion villi biopsy is already extensively used without any scientific trial. Because of such a situation many innovations like gastric freezing, high concentration oxygen for neonates, the use of hyperbaric oxygen in intensive care, insulin coma for the treatment of schizophreniae etc were introduced without evaluation, used and subsequently abandoned after they were proved ineffective or unsafe.

Amniocentesis and chorian villi biopsy remind us their large scale misuse for female foeticide in India. In fact some of the technological innovation appear explictly geared towards use of sexist and racist cultural practices to gain fast currency and early returns on the resultant technology.

Every country that is attemtping to meet the genuine needs of people, has to take crucial decision about selecting appropriate technologies as an alternative to the costly, rendering services to few and profit oriented technologies. In the field, activists are also required to select and develop alternative technologies to provide immediate relief to people. Therefore, in addition to the technology being a political question, it is also a direct practical problem in political practice. This has led many to experiment with various alternative methods of medical care using simple but effective technology and develop models to prove their feasibility. This question is also linked with proliferation of the non-government organisations and needs detailed discussion.

Such experiments in alternative technologies are not limited to using different physical tools but encompass the way medical care is delivered and attempts to humanise it.

Strengthening the Cuckoo's Nest?

A Comment on Mental Health Bill

FREUD and subsequent psychoanalysis, psychotherapy and psychiatry have radically changed the worldview with regard to mental health and illness. Western capitalist countries and socialist countries have largely accepted these changes and have evolved structures and legal provisions that provide a relatively better deal to the mentally ill. However, in all these countries the changes have been within the overall framework of social control, which was anyway the purpose of feudal notions of 'lunacy'.

In India, as in most backward countries, the traditional 'lunacy' worldview is still dominant even within the modern legal framework. Mental health and illness in India was till last year governed by the Indian Lunacy Act of 1912 formulated under British imperialism.

The Indian Lunacy Act (ILA) incorporated only a one line definition of a 'lunatic'—"a lunatic is an idiot or a person of unsound mind"—but had as many as 46 sections dealing with how the property of a lunatic should be administered. Between the period of the enactment of the ILA and the new Mental Health Bill (MHB), passed by parliament in 1966, there have been significant global advancements in explaining, understanding and treating mental illness. But the new MHB in India provides only a cosmetic change over its predecessor. It condemns all mentally ill persons, excluding those mentally retarded, as criminals. The new definition of a mentally ill person is "a person who is in need of treatment by reason of any mental disorder other than mental retardation". Thus, apart from excluding the mentally deficient, the MHB is no different in its basic form from the archaic ILA.

Advances in psychotherapy, psychoanalysis and community mental health care, among other alternatives, are not even mentioned in the MHB. The wide range of mental illnesses is ignored. The monopoly of treating the mentally ill is given to psychiatrists who know very little about alternative therapies. For the psychiatrist chemotherapy and electric shocks or even psychosurgery are the only means for dealing with mental illness. Psychiatrists trained in India do not have any significant exposure to even psychotherapy (with the exception of perhaps those trained in NIMHANS), let alone psychoanalysis and other non-invasive alternatives.

This sole reliance on psychiatrists in the MHB will only further medicalise a problem that has largely social origins. Historically, it has been well established in psychological and sociological research that mental pathology stems largely from society itself. Poverty, exploitation, insecurity, alienation and above all class society itself are harbingers of mental illness.

In spite of this knowledge the MHB is no more than a provision for locking up and managing the property of the mentally ill. It is interesting to note that "property" forms the cornerstone of the MHB as in the case of the earlier ILA. For the imperialist powers the ILA was an important means of controlling and manipulating the power structure by dispossessing many uncompromising landed aristocrats and local power brokers of their property by invoking the provisions of the ILA through which any magistrate could declare a person mentally unsound (without any aid of a medical professional). What the MHB has done is to shift the onus of establishing mental "unsoundness" from the judiciary to the psychiatrist. Thus the enactment of the MHB is consistent with the dangerous trend of the general medicalisation process of human health—*it is more a police bill than a health bill.*

Though on the whole psychiatrists have been critical of the MHB and have demanded amendments, the Indian Psychiatric Society (IPS) has welcomed the medicalisation and the provision in the bill for admission of mentally ill patients to privately run psychiatric nursing homes, besides government owned psychiatric hospitals, which alone were authorised earlier to admit such patients.

In fact the main interest of the psychiatrists in pushing this bill was to gain this provision. This provision too is consistent with the general trend of privatisation. However, in the same breath the IPS has strongly condemned the provisions for licensing and inspection of private psychiatric practice by a state authority—the IPS plans to approach the supreme court to rid the MHB of this latter provision (but it will not challenge the MHB itself)!

Medicalisation and privatisation of mental health care will only worsen the situation for the mentally ill. Further, as regards rights of the mentally ill person there is only passing reference with regard to protecting the patient from 'cruelty' of a practitioner. But this toothless protection is overridden by the fact that the family, state and the medical profession have full control over the patient physically, mentally and socially. The decision-making about diagnosis, therapy, admission, treatment and discharge are vested in the patient's family and doctor. The patient has no say whatsoever in the matter. Therefore a patient suffering from a simple neurotic condition may easily face confinement if the family (for instance in a family property feud) or the state (for instance in case of an ideological adversary or a political prisoner) sanction so on behalf of the patient who supposedly is incompetent to make a decision about his/her well-being.

Thus on the human rights front the new MHB fails completely. If at all, it strengthens control over mentally ill persons clearly abrogating their fundamental rights and implicating them as stigmatised and unlawful citizens.

Hence the MHB needs to be challenged not only by psycho-professionals of all variety but also by civil rights groups, lawyers and social scientists. The MHB's basic form needs to be changed from a social control perspective to a human rights perspective Mental illness and health conditions need to be defined in detail and the independence of the mentally ill person needs to be protected. The protection should have a social basis, and under present conditions can be best ensured with the assistance of civil rights groups and the judiciary. All concerned, therefore must strive to make the MHB biased in favour of the mentally ill and not against them.

Ravi Duggal

Indian Workplace: 'Safe', 'Clean' and 'Healthy'?

A BILL amending the Factories Act has been passed by the Lok Sabha some months ago. While the Bill for the first time accords to workers some rights which had hitherto never been recognised, it needs to be dissected thoroughly. For the present it is interesting to note that even those rules regulations and norms which have been in force for decades continue to be ignored or openly flouted. Take the case of reporting of accidents and occupational diseases. Anyone looking at the data presented year after year in the *Indian Labour Journal*, the official publication brought out by the Ministry of Labour, would marvel at the safe, clean and healthy environment in Indian industry!

Take a look at the accident figures for three years—1981, 1982 and 1984 (the latest). In 1981 there were a total of 3,41,423 injuries of which 740 were fatal. In 1982, 3,02,268 injuries of which 599 were fatal and in 1984 there were only 1,15,442 injuries of which only 381 were fatal. Data was not available for 4 states in 1981, for 5 states in 1982 and for 9 states in 1984. While the figures are not strictly comparable because of inadequate reporting, it is interesting that the proportion of fatal accidents is less than 0.5 per cent in all the years. The accident rate, as everyone but the very naive knows, is extraordinarily low and is in no way related to the real situation. Injuries are reported only when a worker is incapacited by them and thus a large number escape being recorded.

The case of the non-recording of occupational diseases is even more interesting. In 1981 there were 13 reported case of ODs, all of them being chrome ulceration. In 1982, there was a sharp jump in OD with 101 cases—with apparently an epidemic of silicosis (87 cases), all from Madhya Pradesh! In 1984 there was a sharp drop to 27 cases and all of them chrome ulceration again. Even more interestingly, the only state being troubled by OD was Maharashtra for no cases of OD were reported from anywhere else in the country! That the case reporting either of accidents or of ODs is atrocious has been highlighted in these pages some years back (*SHR*, Vol I:3). The article on 'Illness and Accident Reporting in Industry' had pointed out that the reporting has consistently declined since 1960. But is this very surprising given the fact that the number

of medical inspectors of factories had been 11 in 1981, went up to 42 in 1982 and down again to 10 in 1984? Given this kind of situation, what role do amendments ostensibly strengthening the Factories Act play—especially given the fact that workers' health has not been a prime concern in the labour movement in India so far?

PP

Eyesight Problems Among Workers

THE electronics industry is the largest employer in the production sector in Malaysia. Upto October 1986, there were some 70,000 workers, most of whom are women.

Eyesight problems are reported to be occurring frequently and at an alarming rate among workers in electronics factories. Those affected come from the semiconductor assembly section. The work here requires the workers to use microscope daily to tie wires to pieces of semiconductors which are almost invisible to the naked eye.

According to a survey published in the book, *Health Hazards in Electronics* by Thomas H Gassert, 44 per cent of the workers in American-owned electronics factories in Malaysia complain of eyesight problems while 42 per cent complain of headaches.

The survey revealed that the eyesight problems are due to the use of microscopes and TV monitors as well as exposure to chemical vapours, smoke and dust on a long-term basis.

Eye diseases such as conjunctivitis are caused by chemical vapours and can spread from one worker to another because the same microscope is used by several workers. This problem is made worse by the long hours of work. Salaries and bonuses are paid based on a quota system and the quality of work done. Hence, many workers may be driven to work hard, without sufficient time or rest.

The survey also found that many companies do not teach the staff the proper use of the equipment. Microscopes and TV monitors which are defective are also not repaired.

Noisy machines can also harm the electronics factory workers as the noises can lead to hearing loss and can cause tension which will lead to other health problems.

In electronics factories, some machines such as the metal stamping machines and the packaging machine are very noisy. The use of ultrasound to tie and test components also emits noise at a high level.

The safe level of noise, according to *Health Hazards in Electronics*, should not be more than 60 decibels and 16 kilohertz for an eight-hour working period.

The book says that loss of hearing among electronics factory workers is due to prolonged exposure to a noise level above 80 decibels.

This exposure can also cause tension which will eventually lead to other problems such as hypertension, increased heart-beat, vein disorder, irritability and a lack of concentration. All these in turn may lead to accidents at work, cause muscular tension, nausea and headaches.

Utusan Konsumer, March 1987

Campaign to Ban Hazardous Drugs

THE Drug Action Forum, West Bengal has initiated an interesting campaign for a ban on the manufacture and sale of unscientific and harmful fixed-dose combination of chloramphenicol-streptomycin. They have been circulating a letter to manufacturers requesting that they stop manufacturing these products. The letter is signed by 270 practitioners of West Bengal and sets out the reasons why they feel a ban is necessary.

The letter points out (1) that the combination has not been recommended against diarrhoea in any standard textbook of medicine and there is no scientific basis for such use; (2) that chloramphenicol is a valuable drug, the drug of choice for typhoid and its indiscriminate use may cause the development of resistance to typhoid bacilli; (3) that streptomycin is not absorbed through the gastrointestinal tract and is besides a first line drug in the treatment of tuberculosis and is in perpetual short supply; and (4) that there are many effective alternative treatments for diarrhoea when needed.

Women's Health Care in Brazil

carmen barroso

In 1982, the ministry of health in Brazil decided to present a comprehensive programme of women's health. The programme was drafted by four doctors, two of whom were feminists and clearly reflected the politics and the philosophy of the women's movement as it had been evolving in the previous decade. The author who was closely associated with early efforts in this direction writes about the problems encountered in evolving the plan and in implementing it.

BACK in 1982, I was helping the electoral campaign of a candidate for governor in the state of Sao Paulo, and together with a handful of other volunteers, I was in charge of drafting the items on women's health to be included in his campaign agenda. It was not easy, I can tell you!

To begin with, the very legitimacy of having a special programme for women was questioned. Again and again we had to argue that yes, all human beings are entitled to good health care, *but* women do have special health needs, both because of their biological reproductive functions and because of the sexual division of labour prevalent in our society. Other arguments had to do with priorities and there we were repeating that: Yes, we knew that infant mortality rates were unaceptably high, *but* did they know what maternal mortality rates were? Or: yes, we agreed that work-related accidents and illnesses that reached both men and women should be greatly diminished, but wouldn't they also agree that women did have a right not to have to resort to clandestine abortion?

When feminism, after decades of demobilisation, reemerged in the Brazilian political scene in the mid-seventies, the overall national priority was the struggle for democracy and the prevailing idea was that a focus on women's specific issues was divisive and self-defeating. Even where women's subordination was acknowledged, it was dismissed as an unimportant political question, a mere byproduct of class exploitation or a cultural tradition that would naturally disappear as a consequence of the development process. Forgive me the oversimplification but, as I said, I am referring to the prevailing ideas, those that set the climate where a project can grow or fade away. And feminism managed to flourish quite well thanks to a strategy of downplaying women's specific issues and to restricting them to those in the sphere of production. It thus managed not to alienate important partners in the struggle for democracy: the left and the catholic church.

But, by the end of the seventies, it was not possible to continue ignoring women's daily struggle to control their reproduction. The fertility rate was going down quite rapidly. And that in all regions of the country, in all social classes, and even in the rural areas. The demographic figures only became available several years later, but whoever had any contact with the poor soon became aware that pills, tubal ligation and clandestine abortion—no matter their high costs—were more and more widespread. And what was more surprising was that Mothers Clubs and other grassroots organisations—most of which had been created in the sixties under the umbrella of the catholic church—having evolved from their traditional handicrafts and religious activities to the active mobilisation to press local governments for urban services, were now presenting a new demand. Can you guess what? Sex education! The rationale presented was that they needed information in order to guide their children. But as soon as the question period was open after a given lecture, the issues that used to come up were those of frigidity and power relations between the couple.

Why did these problems begin to emerge in public? Intensive migration and the growth of megalopolis had resulted in the severing of traditional family ties and neighbourhood groups. That, together with increasing work alienation, had helped to raise the expectation towards couple relationships as a major channel of personal fulfilment. Besides, women's access to the mass media—especially to TV romantic *novels*, which were reaching 75 per cent of urban homes in 1980—all acted together to question the use made by many men of women's bodies. The word *use* does not reflect my intention to shock you: it is the common euphemism used by rural women to mean sexual relationship (and that certainly tells us something about the quality of this relationship!). To cut a long story short: the fact was that tensions were mounting in the bedroom, and these were showing up in group discussions whenever poor women had an opportunity to speak.

The year 1982, as you know, was when the debt crisis came to the forefront and the country had to resort to the IMF structural adjustment policies. As always happens in crisis situations, the old neo-malthusian ideology came out of the closet again as an apparently easy solution to the difficult economic problems. In 1983, sectors of the military, together with private family planning organisations drafted a plan to curb population growth. This raised the same fears prompted by similar attempts made in the sixties and seventies. The major fears were: diversion of government efforts from the root causes of poverty, foreign intervention on national priorities and open doors for coercion of poor people to have fewer children.

But at that point those arguments were no longer strong enough to resist the creation of government programmes. On the one hand, the advantages of fast population growth, an argument which was popular in the sixties, had long been discredited. On the other hand, contraceptives were widely available to those who could buy them, and it was difficult to deny that, in the absence of government support, poor women were going through tremenduous sacrifices in order to regulate their fertility.

What happened then was that, instead of just opposing the population control plan, the ministry of health decided to present an alternative: a comprehensive programme of women's health. Drafted by a committee of four doctors, two of them feminists, the programme embodied a set of principles the women's movement had been formulating through

its practice in the previous years.

It started with a thorough diagnostic of the causes of mortality and morbidity among women over 10 years of age, which numbered around 45 million in 1980. Free health services provided through the public system or through the social security system had been mostly limited to pre-natal and natal care, and grossly inadequate both in terms of coverage and quality. The new programme was based on the idea of comphrehensiveness. Services should not be restricted to reproductive functions, they should include cancer prevention and the control of sexually transmitted diseases, and be integrated with general clinical care. Married women of fertile age were not to be the sole clients. Older women and adolescents were also to receive adequate care. And public services should include both the provision of information and all means of contraception and infertility treatment.

An important element of the preventive aspect was the educational component. In order to enable women to take control of their own health, they should have access to needed information. But much more than that, they should have the opportunity to develop the attitudes conducive to the effective use of this information. That is, instead of the prevailing authoritarian doctor-client relationships, health services should contribute to the enhancement of self-esteem and self-respect, so that women could have pleasure in taking care of their own bodies.

All this was very beautiful and very nice on paper. But a small and inexperienced staff at the ministry of health had to spend an enormous amount of time in political negotiations to make the programme viable. Opposition came from two main sources: at first, from the democratic sectors who did not trust the military government and suspected the programme to be just another disguised population control initiative. This mistrust vanished gradually with increased transparency of the decision-making processes and the election of Tancredo Neves in 1985.

The other sector was the catholic church, whose teachings have little impact upon the practices of the members of its congregations, but whose hierarchy is very vocal. The ministry diligently courted the church and apparently managed for a while to get its agreement to look the other way But the church became very active again last year, when the social security system jointed the programme. The church efforts are now aimed at restricting the availability of what they consider unethical methods of contraception, that is, barriers, pills, IUDs and all others not based on periodic abstinence.

But, in spite of this resistance, some important achievements have occurred. What has been most remarkable has been the adoption by the health system of educational practices developed by the women's movement. It is now quite well-established that doctors, nurses and semi-literate health assistants, all need refresher training, and many in-service programmes throughout the country have aimed both at technical updating and at clarification of attitudes and values.

Educational materials originally developed for consciousness-raising groups have been widely used in small-group discussions where health workers of all ranks have, for the first time, a chance to analyse critically their practices and assumptions about women as clients. The techniques used put an emphasis on respect for differences of opinion among group members, and are quite revolutionary in the sense that they cut across hierarchies in the workplace.

Another important innovation is that sex education is now a key element of the training programmes. Reproductive health issues cannot be separated from sexuality. Just to give an obvious example: if a woman cannot use a diaphragm because she cannot bring herself to put a finger inside her vagina, nothing will be accomplished by technical instruction. So sex education starts by re-examining the educational practices of our society that taught us to have shame and fear of our own bodies. And this, of course, is related to women's role in society. Therefore, a little history of Brazilian women is introduced in some of these training programmes.

As most health workers are themselves women, their evaluations of the educational programmes often point to self-awareness as an important by-product. But the ultimate aims of those programmes are two-fold: first, to influence the overall attitude of the worker towards the clients, who should be respected as autonomous human beings in charge of their own health and reproductive decisions; and second, to prepare the workers to conduct similar training sessions with the clients. This has begun to happen in many units, but it still depends largely on the initiative of interested workers.

An evaluation carried out in late 1986 pointed out as the major achievements of the programme, the development and printing of educational materials and norms of clinical procedures. These norms refer to sexually transmitted diseases, pre-natal care, breast and cervical cancer prevention. Family-planning norms have been developed put are not printed yet. Norms for childbirth are still in the drafting. The programme has also supported the development of national technology in the areas of spermicides and diaphrams. However, the units where the programme has been effectively implemented still are not more than a hundred, distributed among a few states.

What lies ahead for the future? I think it will depend on three widely different factors. First, the success of the programme requires an administrative reform to give it efficiency it now lacks. As it stands now, the decision-making is highly centralised and the decision-process quite bureaucratised. And this, of course, has greately delayed its launching at the local level.

Secondly, the future of the programme is tied to the future of the women's movement in at least two ways. Women will have to remain active as a pressure group at the central levels of government so that the the church hierarchy does not succeed in curtailing the scope of the programme. On the other

hand, at the local level, clients increasingly aware of their rights will have to keep a constant eye on the quality of the services to avoid abuses and a tragic gap between intent and consequences.

Thirdly, resources for the programme depend on the solution to the debt crises. At the moment the programme is mostly supported by a five-year grant from UNFPA. But even so, the programme relies basically on the smooth running of the public health services. And, as you probably know, Brazil has been exporting capital to the industrialised countries in the last few years. A large proportion of the GNP is going to service the debt, the balance of payments is going down due to increasingly unfavourable terms of exchange, government revenues are being sharply cut. In this scenario, institutional stability is threatened. At the level of the health services, a most likely outcome is a sharp drop in the already low salaries of health workers. They become demoralised and spend a large proportion of their time fighting against salary cuts.

If common sense prevails, and new economic agreements allow the economies of the third world to resume growth, the Brazilian health programme will be strengthened, its difficulties corrected. Since it corresponds to such great needs, and it has been drafted with such audacity and care, it deserves this chance.

STATEMENT about ownership and other particulars about newspaper RADICAL JOURNAL OF HEALTH to be published in the first issue every year after the last day of February.

FORM IV *(See Rule 8)*

1 Place of publication:	Bombay
2 Periodicity of its publication:	Quarterly
3 Printer's name:	Amar Jesani

Explosion of Alternative Information on Drugs

CAP Reports on Drugs and the Third World. *Chloroform—Sale and Hazards: a Malaysian Study*; no 9: *Pizotifen—Double Standards in Marketing*, no 11; *Cyproheptadine—Risks and Unethical Marketing in Malaysia*, no 12; *Stanozolol—Toxicity and Unethical Marketing in Malaysia and the Third World*. Consumers' Association Penang, Malaysia, 1986.

Consolidated List of Products Whose Consumption and/or Sale have been banned, withdrawn or severely restricted or not approved by governments, II Issue, UN, 1987.

IN the last couple of years, with the emergence of a vocal and visible consumer movement all over the world, has come about something of an explosion of alternative information in these areas. Until very recently, information about consumer products, etc, was the monopoly of the industry. Even the governments of most third world countries did not have access to data such as the hazardous nature of a drug, its side-effects if any, whether the drug was banned in other countries of the world, etc. This had a direct impact on the drug consumer movement in that the arguments of the drug companies were difficult to counter in the absence of relevant alternative information.

Thus breaking the information monopoly has become one of the prime objectives of the consumer movement, especially the drug consumer movement. Most groups all over the world have been producing volumes of literature which is very useful in showing up the drug industry for its unethical practices. All the publications under review fall into this category and are themselves a reflection of the growing strength of the movement.

The Consumer Association of Penang (CAP) brought out a series of reports in 1986 aimed at providing the public with the results of some of the important areas of CAP's activities.

The first of the series is on chloroform. The study finds that in Malaysia "despite all the documented evidence of its dangers, chloroform is present in many products". Strengths below 10 per cent are exempt from the Malaysian Poison Ordinance 1952 and the Poisons List 1983. Chloroform is a commonly used ingredient in cough preparations. Interestingly, the Drug Index for Malaysia and Singapore lists only three preparations under chloroform containing products. And yet the study has found numerous others in the market. It has also drawn attention to the inadequate information available especially with reference to the hazardous nature of the product, particularly when consumed by children. A review of the advertising of these products in the lay press has also been undertaken. Of the other three booklets, two are on antihistamines and one on an anabolic steriod. All the three were presented to the ministry of health, Malaysia in July 1986. In October the government announced that these three drugs had been banned. Manufacturers and distributors were given three months to withdraw all products containing these drugs.

Although pizotifen, an antihistamine, is classified as a Group C poison, the study group found that it could be easily bought over the counter. The drug used in the treatment of migraine in developed countries is heavily promoted as an appetite stimulant in Malaysia. No contraindications are ever mentioned. Similar is the case with cyproheptadine, another antihistamine drug. In the US only one preparation of the drug, Periactin is marketed and is indicated for use in allergy conditions and as a supporting drug in anaphylactic reactions. The study finds that the company, Merck, Sharp and Dohme is practising double standards in its marketing of the product in developing countries.

The Consolidated List is in a sense a triumph of the drug consumer movement all over the world. In 1982, because of pressure from these groups, the UN General Assembly "aware of the damages to health and the environment that the continued production and export of products that have been banned and/or permanently withdrawn on grounds of human health and safety. . . is causing in the importing countries" and because many of these countries lack adequate information suggested to the secretary-general that a Consolidated List be prepared of products whose consumption and/or sale have been banned, withdrawn or severely restricted or not approved by governments. The list was to be easily readable, and was to contain both the generic as well as brand names. Needless to say, this sent shock waves through the multinational drug industry. The pressure that was put on the group entrusted with the task to leave out the brand names, is a telling illustration, if one were needed, of the enormous political influence that the industry wields on governments in the developed countries as well as in the third world.

The first issue of the List came out in December 1983 and again was the target of much flak from the industry and vested interests. The Coordinating Committee had to make a sustained campaign to scuttle the industry's move to do a hatchet job on the List, and all such future publications.

The current List is a 655 page volume listing 600 products (100 more than the last one). It is basically in three parts—pharmaceuticals, agrichemicals and industrial chemicals. It records the status of each of these products in all countries (or at least as many as have provided the information). At the end of the volume is a list of brand names of these products.

It must be stressed that this is the first time such information is available in a consolidated manner in one volume. Every effort must be made to keep the initiative from being killed. For one thing, governments either because of the usual bureaucratic problems or because they are under pressure from vested interests, are not very prompt in providing information about changes in legislation regarding particular products. It is here that voluntary groups could play a role.

Workers' Health and Labour Militancy

gerald markowitz

The Struggle for Workers' Health: A Study of Six Industrialised Countries by Ray H Elling, Baywood Publishing Co, 1986, 500 pages, $ 37.50.

US workers face a multitude of dangers on the job and the Reagan administration has been largely successful in hobbling the Federal Occupational Safety and Health Administration (OSHA) and state regulatory efforts. This book puts the problem in an international perspective, with very disturbing results. Elling shows that even at its best, OSHA compares very poorly with other capitalist countries' occupational safety and health systems.

Elling uses a Marxist framework to analyse occupational safety and health (OSH) problems: "Most if not all OSH problems stem from the inequitous exploitation of relatively powerless workers engaged in producing value which is expropriated for the private use of a ruling elite," he states. Elling surveys the history and political economy of the countries he studies, and details the OSH system in each. The countries studied are the US, Britain, the German Democratic Republic (DGR), the Federal Republic of Germany, Finland and Sweden.

Elling compares six elements in the countries' OSH systems: policy, sponsorship and control, education, organisation, information and financing. He concludes that Sweden and the GDR have developed the most comprehensive systems for protecting workers' health; Finland's system is somewhat less strong. Britain and the Federal Republic of Germany rank much lower, and the US offers workers the least protection, he concludes. While acknowledging that his conclusions are tentative, Elling's analysis is extremely useful for both activists and researchers.

Elling maintains the single biggest factor determining the quality of a country's OSH system is the strength of its workers' movement. In Sweden, for instance, 95-98 per cent of blue-collar workers are organised and 70-75 per cent of other workers are unionised. As a result, Sweden has developed a system that is light-years ahead of the US (where only 18 per cent of workers are unionised).

Swedish policy seeks to insure that employment is fitted to the health requirements of workers. Sweden's concept of health is also unusually broad, taking into consideration not only physical conditions but also the use of "piece work, shift work, incentive systems, and psychosocial factors related to physical and mental illness." For instance, Swedish research has shown that the degree of control workers have over their work affects their rate of coronary disease.

At the core of the Swedish system are 1,11,000 safety delegates elected through their unions. There must be a delegate in every plant with at least five employes. These delegates are empowered to interrupt work that poses an immediate or even long-range danger to workers. Every workplace with over 50 employees must have a joint labour-management safety committee in which workers are in the majority. The committee helps hire plant physicians and safety engineers. Sweden's system cannot even be compared to the US's non-system. Here, only workers who are represented by health and safety conscious unions like the Oil, Chemical and Atomic Workers can expect protection. Even so, Elling notes that Swedish workers are subject to some of the same pressures as those in the US. Even in Sweden, workers can be cowed by management threats to move or shut down in the event of costly health and safety demands.

Elling suggests that only a revived and militant labour movement can improve the US's abysmal health and safety system. But by describing what workers have won in other capitalist countries, Elling shows that the fruits of struggle can be crucial to workers' well-being.

Gerald Markowitz is coeditor of "Dying for Work" (Indiana University Press) and "Slaves of the Depression: Workers' Letters About Life On the Job" (Cornell University Press). Baywood Publishing Company is at Box D, 120 Marine St Farmingdale, NY 11735. Reprinted from *The Guardian* (US), August 8, 1987.

Systems Approach to Problem-Solving

Agencies Working Together: A Guide to Coordination and Planning by Robert Ross, Kevin Gilmartin and Charles Dayton, Sage Publications, 1982. Price $ 7.95, pp 119.

THIS publication is part of the Sage Human Services Guides Series (Vol 28). It is an attempt at delineating various approaches to inter-agency coordination based on an actual study of such coordination in the state of California. With a spate of NGOs working in the field of 'human services' the need for effective communication and coordination between various agencies, so that they can help each other, also increases. In essence this book is a guide written for all sorts of welfare and social service agencies. It discusses various methodologies and approaches 'tried out successfully' that can help build up effective inter-linkages between agencies in order to provide better services to their clientele.

The book is useful for those who feel that a systems approach solves most problems in management.

Medicine in USSR
Analysis Lacks Rigour

anant r s

BOB DEACON's 'Medical Care and Health under State Socialism' (*RJH* Vol I.1) starts on a very sound note. In the first part, it separates six main aspects of socialist health care and shows that there is much more in real socialist health care than what the traditional left thinks it to be—widely available and almost free medical care. An analysis of medical care in any post-revolutionary society would be inadequate, unless it systematically goes into the aspects dealt with by Deacon. I would add two more aspects to a really socialist communist health care: (i) rational use of drugs and other medical facilities (investigations, hospital-beds, etc), (ii) a clear break from a medicalised attitude towards healthproblems (an attitude which believes that 'there is a pill for every ill', and still worse looks upon all deviations from the upper class white male model as abnormal or even all physiological phenomenon as health problems to be solved by medical therapy).

In analysing the Soviet medical policy, however, Deacon is not careful, or rigorous enough. The empirical basis of his conclusions is, therefore, quite problematic.

For example, he makes the usual mistake of comparing Soviet Union with advanced capitalist countries—the European Economic Community. This is an ahistorical comparison. These EEC countries were far ahead of Russia at the time of Revolution in 1917, and hence we should compare Russia of today with say Portugal or Italy which were also like Russia, quite backward, at that time. The USSR is even today backward in some respects as compared to the United States or some imperialist European powers. This in itself does not mean at all that Russia is not socialist or socialism is worse than capitalism.

In assessing whether or not USSR is spending 'more' money on health care, Deacon makes a second added mistake of taking the medical care expenditure of capitalist countries as 'standard'. It is well known that advanced capitalist countries were overusing drugs and other medical facilities, that the medical-industrial complex is a big racket. Hence if a country is spending less on medical care than these stupid civilisations, that by itself cannot be taken as a bad thing. An appropriate indicator would be to find out what percentage of medical needs are being met and in what manner. Admittedly this is a difficult indicator to quantify and we may not get proper, comparable data about this. But some rough estimation can be made. A rough estimation in a proper direction is better than a precise estimation in a wrong direction: If medical expense as an indicator of better care is to be taken, then the comparison has to be made with the pre-revolutionary situation. Finally, we must remember that the ultimate aim of a socialist society would be reduce the necessity of medical care and hence the relative proportion of medical expenses as well.

Deacon has properly drawn attention to the both 'relative and absolute rise' in USSR in the so-called 'disease of modernisation' like cardiovascular diseases and cancer. But more information is needed to draw valid conclusions. As infectious diseases decline, even in a really socialist society, more people are likely to die of degenerative disorders. In the imperialistic countries a very large number of people die prematurely (in their forties or fifties) of these degenerative disorders because of the unhealthy 'American way of life'. One must know whether such a premature morbidity and mortality in the USSR exists or not, is rising or not and whether (like in western capitalist countries) it can be traced to wrong kinds of food, work environment, social environment and so on. The rise in the USSR in "the age-adjusted death rate by 18 per cent over last decade" as quoted by Deacon is an indicator. But we need more information before drawing valid conclusions.

Deacon's article contains hardly any information about whether or not the domination of doctors as experts, over paramedics and the patients, the philosophy of 'the-doctor-knows-all-and-hence-will-decide-all' has decreased in the USSR or not. The lowering of the status of doctors in terms of their pay-scales and privileges is different from changing the role of expertise. In the absence of proper specific information on these aspects (point numbers nine to twelve in his table no III), his conclusions on these points cannot be taken as valid.

If all these and such points are rigorously taken into account to find out the *trend* (and not merely a static picture in a particular year), one has a hunch that one would come to the same or even more critical conclusion than Deacon's. USSR is a state socialist society which has gone far ahead of many comparable capitalist societies but cannot be called a socialist society in the sense in which Marx understood this concept. But one must be aware that Deacon's conclusions in this article are not based on solid evidence.

Lastly, a word about the sexual division of labour in medical care in the USSR. As pointed out by Deacon, 90 per cent of primary health care physicians in the USSR are women. This is quite in contrast to capitalist countries wherein males overwhelmingly predominate in this position. But in the USSR, in the thirties and forties, the status and pay-scales of engineers and scientists were kept much higher as compared to doctors since the planners gave higher priority to these skills. This tradition still persists, though it now appears to be changing. Men predominated in these more prestigious, more paying fields and women went to less prestigious, less paying positions of doctors. This shows that though USSR has got over the typical sexual division of labour as found in capitalist medicine, a different mode of sexual division of labour has taken its place; and has stabilised—something one does not expect in a truly socialist society. Deacon has missed this point in his discussions of medicine in the USSR.

Politics of MCH

padma prakash

MANISHA GUPTE's article (*RJH*, I: 2) provides a broad framework for analysing health policy vis a vis women. The needs of capitalist accumulation mediate through patriarchal structures and relations suppressing women's rights to health and reproduction. This mediation takes different forms in different societies. In a country like India, it is interesing to look at the process by which the needs of capitalist development have simultaneously strengthened and altered patriarchal structures. It is especially necessary to take cognisance of the manner in which the Indian state has coopted and adapted the demands of a 'democratic' polity for its own purpose. The history of maternal and child services in India provide an illustrative example of this. In the evolution of policies and programmes directed at the welfare of mothers and children especially in recent years, it is possible to discern the way in which the state has, responded to the growing influence of the women's movement and has accomodated the demands of the increasingly vocal and influential consumers of health care. 'Programming reproduction' is just one aspect of MCH services. Further, there is also the question of how progressive movements must view such policies and programmes.

As early as the mid-nineteenth century concern for maternal health motivated a series of efforts. This concern was, of course, somewhat spurious. Introducing 'modern' methods of maternal and child care had served multiple objectives. Firstly, it was seen as a means of approaching women so as to "educate them. . . show them the beauties of christianity, for only then would the regeneration of India be a reality and the conversion of its people an accomplished fact".

Secondly, the MCH movement in India even in its limited spread, enlarged the base of operation of 'scientific' medicine which in England was becoming highly organised and sex and class biased. The MCH rhetoric of the time saw indigenous maternity practices as the main cause of the high maternal mortality and held modern practices, especially in hospitals not only as being progressive but safer and more hygenic. It was to staff these new lying-in hospitals that Indian women were encouraged to take up medicine. This is especially ironic since at about the same time women in Britain were fighting bitter battles to be allowed to train for and practise medicine. Clearly the move in India had little to do with encouraging women to enlarge their sphere of activity in society, but more with the needs of the colonial government.

Thirdly, the promoting of modern maternity practices through the MCH movement fitted well with the philosophy of the reform movement advocating women's education in India—so that as mothers they would be capable of giving birth to and bringing up a new generation of progressive Indians. The MCH movement became a vehicle for bringing about this 'regeneration' of India for both the British and the Indian liberals although it meant different things to the two. Its outreach however, was confined to the upper classes in the urban areas in the presidencies. Needless to say it hardly had any impact on the maternal mortality or child mortality in the country.

MCH continued to be a priority area in the health policies of independent India. The Bhore committee continued to view these services as not only a measure for reducing maternal mortality but as a necessity in order that women could adequately perform the function of motherhood. Facilities for the protection of women's health in the 'productive' sphere were mainly meant to ensure her 'reproductive' adequacy. But at the same time the maternity and child welfare centre "with its combined attack on the health and social problems of the Indian home" was expected to play a vital role in the programme of 'national reconstruction'.

Increasingly however, investments in the reproductive health of the woman became far more important than her health in the factory or the field. "The protection of the health of the expectant mother and her child" (irrespective of whether she occupied a place in the sphere of production) became of paramount importance "for building a sound and healthy nation". The mother became officially recongised in policy as the channel for 'educating' the entire family. After this although MCH continued to be a national programme its focus became increasingly narrow and its implementation poor. Quite apart from the fact that MCH programmes did not recognise the real causes of maternal mortality their impact on the section of the population which accounted for a large proportion of maternal deaths was minimal. Interest in MCH also began to decline. (For example, there were hardly any ICMR research projects in the area after the mid-sixties. This disinterest in the health of the mother is manifest even in those areas outside MCH which had some import for maternal health. For instance, research in anemia—increasingly the focus became narrow and oriented towards developing quantification methods which all but ignored the real problems in the area.)

Recent years have seen a revival of interest in MCH which has to be seen in the context of other developments such as the status and location of women, the current priorities of the state as well as the pulse of popular/mass movements.

In the last decade a great deal of attention became focussed on women's status and issues affecting their status. This decade, the UN Women's decade ironically enough, also saw a deterioration in the economic situation of women. Much work has been done on how the development processes have in fact been the cause of women losing their jobs and the means of livelihood—as for instance happens when the introduction of new technologies in agriculture results in women having to give up their traditional occupations, or when modernisation of processes handled by women in industry results in the loss of jobs.

At another level, the only sector which has recorded a growth in employment, the service sector, has also registered a significant rise in women's employment. In other words it would not be wrong to infer that while the

economic and social status of women of the labouring classes is rapidly declining, women who have access to formal education, generally from the better-off layers of the urban working class and the middle class, are finding jobs in the expanding service sector. This in turn contributes to the growing purchasing power the middle class which provides a market for the products of the expanding consumer industry. This factor has to be kept in mind when assessing the purported objectives and the real impact of any programme such as the MCH.

Secondly, there is the undoubted impact of the women's movement not only on national policies but internationally as well. The movement has had the result of highlighting the low social, economic and health status of women. Indices such as maternal mortality suddenly became major issues which needed to be tackled or at least should appears to have been dealt with.

Thirdly, the health status, health care structure and the priorities of health care have undergone a change. One could well hazard a guess that the class differential in health status has become sharper than ever before (See for instance NIN's nutrition surveys which actually shows a decline in consumption levels—although of course, the NIN has grossly tried to cover it up). Inevitably the sex differential in health status would also have sharpened. As a consequence the class biases in health care delivery have become clearer. In addition, the trend towards increasing privatisation as well as the more widespread use of the fee-for-service principle even in state health services will aggravate the disparities in people's relative access to service. Inevitably of course, the priorities of health programmes have also changed.

All this has to be taken into account in understanding the real nature of MCH programme. Because the state needs to sustain the growth of the purchasing power of the expanding middle class, women's employment in certain spheres is a desirable goal. Thus health care for women so that they are able to handle the two spheres of activity becomes a necessary service which the state accepts responsibility for. Promoting the small family norm is again desirable—both so that resources can be optimised as well as because the process of socialising children to fit into patriarchal society can take place efficiently.

Thus for instance, quite clearly, the nutritional supplement component of these programmes is irrelevant to the section of the population who cannot obtain two full meals. Pumping an expectant mother with vitamins when she has abominably low calorie intake is an absurd exercise—and the state is well aware of it. The component is really meant for a different class—the small farmer/lower middle class, where there is just about sufficient food but not enough to take care of the extra needs of pregnancy. On the other hand, the anganwadi programmes may well be used by all sections, including the poorest women who may then be 'released' to work the fields without encumberances or alternatively at the EGS sites thus increasing the numbers on state dole (which accrues to the image of a welfare state).

But most importantly these programmes are redifining and restructuring the role of women in patriarchal class society at the present juncture. Beginning with the breastfeeding campaign, the immunisation programme and the anganwadis, the woman's role in the upbringing of the child is being redefined. The concept of the family with its hierarchies as the primary socialising institution in capitalist patriarchal society is being reemphasised. Investments of all kinds in the family and in children are rising. In order to ensure the continued existence of the family, the ruling class has to reetch the female stereotype which will accomodate the new feature of an employed mother and wife. The setting up of a department for women and children cannot be regarded merely as a response to the pressures of the women's movement. It has a necessary role to play in drawing up a new image of Indian womanhood. It is in this context that we have to assess any programme, whether in health or otherwise, directed at women.

How then do we regard these programmes? Should we reject them entirely? Or can elements of these be used to advantage to weaken the very structures which the state is trying to strengthen?

While this needs to be tackled in a more elaborate manner, here are some pointers . For one thing, any critique of state services—especially in MCH—must ensure that the trends which emerge as a result do not reject state services by opting for more expensive and perhaps less efficient private care. This will only mean that the tendency of the state towards ridding itself of its welfare obligation will get an added boost. On the other hand, by highlighting the inadequacies of the service, there is an opportunity to initially pressurise for better service but in the long run also to show up the non-viability and insincerity of the welfare goals.

At the same time the sexist and class bias of these services also need to be brought out in the open. The fact that these programmes project a model of Indian womanhood which reinforces existing norms which themselves need to be challenged is a task that the health groups and the women's movement must take seriously. And this is a difficult challenge—it comprises not merely in confronting the real objectives of state services, but in tackling the inherent sexist and class ideology of the medical establishment.

IN SEARCH OF OUR BODIES

Feminist View of Health and Reproduction in India

Papers presented at the workshop on "Women, Health and Reproduction in December 1986 organised by Shakti. Plus the invigorating discussions which threw up myriad questions—more questions perhaps, than answers. And that is the best way to begin the search for our bodies, by peeling away the layers of myth and mystique which have distorted our understanding of ourselves as women.

MEDICO FRIEND CIRCLE PUBLICATIONS

Medico Friend Circle Bulletin (Monthly) :
Annual Subscription: Rs 15

Anthologies:

In Search of Diagnosis	Rs 12
Health Care: Which Way to Go	Rs 12
Under the Lense	Rs 15

Bulletin subscriptions to be sent to C Sathyamala, F-20 (GF), Jangpura Extension, New Delhi 110 014. Orders for the anthologies to Dhruv Mankad, 1877 Joshi Galli, Nipani, Belgaum Dist, Karnataka.

SUBSCRIPTION RENEWALS

Our new subscription rates.
For individuals—Rs. 30/- (four issues)
For institutions—Rs. 45/- (four issues)
Foreign subscriptions: US $ 20 for US, Europe and Japan
US $ 15 for all other countries (special rates for developing countries)
Life subscription: Rs. 500/-

D.D.s, cheques, IPOs to be made out to *Radical Journal of Health*, Bbay. Please write your full name and correct address legibly. And please don't forget to add Rs. 5/- on outstation cheques.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or Marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet: This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (for issues). I am sending Rs._____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

On Headaches

It's beautiful to be a communist
even though it gives you lots of headaches.

And the thing is that the communist's headaches
are supposed to be historical, that is to say
they don't go away with aspirins
but only with the realization of Paradise on Earth.
That's how it is.

Under capitalism our heads ache
and they decapitate us.
In the struggle for the revolution the head is a time-bomb.

In the construction of socialism
we plan headaches
which doesn't make them any less frequent, just the other way around.

Communism will be, among other things,
an aspirin the size of the sun.

Pharmaceuticals: Limitations of Left Perspective

WHAT are the issues that arise when we are discussing the relationship between pharmaceuticals and health? There are three types of issues. First, the issue of the general relationship between pharmaceuticals and health. Second the role of pharmaceuticals in capitalism, and especially monopoly capitalism, as well as that in state socialism and revolutionary socialism. Third, the objective and the standpoint of the Left movement in India as regards this issue of pharmaceuticals and health. Let us take a brief overview of the various sub-issues involved in these three aspects of this problem.

Contrary to what the drug industry or the technocratic ideology would like us to believe, drugs have played a marginal role in improving or maintaining the health of the people. In a way this is obvious because it is clear that health-status basically depends upon food, water, sanitation, environment, working-conditions and cultural atmosphere. Moreover, until recently, therapeutic efficacy of medicines was very low. In ayurveda, the ancient Indian approach to health and disease, what is notable, (given the primitive tools of enquiry available in those days and given the dominance of idealist tradition), is its materialist outlook—not much scope for spirits and the like. It is however a controversial issue as to what extent ayurvedic medicines have been effective and safe. That they have been used for hundreds of years does not necessarily mean that they have been effective and safe. In the west things were probably worse. Medical professionals had very few useful medicines to offer to the patients (less than the folk-people had) till as late as late 19th century. Many of the remedies were of the nature of blood-letting, branding and the like or use of corrossives or other drastic and harmful substances as medicines.

The era of safe and effective antimicrobials, anti-biotics, started from 1930s and most of the antibiotics and other 'wonder drugs' came after the second world war as a part of the third industrial revolution and post-war restructuring of the imperialist system and its boom. By this time, however, most of the major infectious diseases in the west had already declined substantially. Now it is well-known in informed circles that modern drugs have thus not played an important role in the improvement of the health-status in the west. It is basically the improvement in the general living standards (food, sanitation, housing, work, education, etc.) which did the job. In the developing capitalist societies, these powerful catalytic agents—the modern pharmaceuticals including most importantly the vaccines—have hardly realised their potential because the socio-economic conditions are inimical. This can be seen from the case of megapolis like Bombay. Here we have drugs and doctors (including specialists) available in every lane, but tuberculosis, leprosy, venereal diseases and even polio show to sign of the respite. China, which is a quite comparable out of the capitalist straight-jacket has shown how modern drugs can be a powerful aide in the rapid control over the scourge of infectious diseases when social conditions are favourable for such a control.

The so-called 'diseases of industrialisation' (which are the diseases of monopoly capitalism and the culture it breeds—cardiovascular diseases, injuries due to accidents, cancers, diseases due to obesity and psychiatric problems—cannot be cured with drugs. On the contrary, the overuse of drugs in such disorders lead to a number of iatrogenic health problems.

It may be argued that the above is a rather simplistic statement. Yes, indeed, it is; it being a brief statement of a standpoint about a historical phenomenon or trend. There are some phenomenon which do not quite fit into this scheme. But that does not alter the overall picture. Secondly, to point out the marginal role of medicines in improving health status of population is not a criticism of modern medicines but of technocratic, self-servicing ideologues who overplay the role of medicines. There is no doubt that modern medicines have a tremendous catalytic potential and even in absence of favourable social conditions, they have made human life more tolerable that what it could otherwise be. But its wrong to attribute more than this to medicines.

The question of the role of non-allopathic medicines is a perplexing one. Homeopathic and allopathic medicines have entirely different presuppositions, are of entirely different nature, both qualitatively and quantitatively; yet both help in different degrees and instances the human body in its recovery from illness. It is a theoretical puzzle as to how this can happen. This discussion cannot, however, be separated from the one about different disciplines of medical care—homeopathy, ayurveda, unani and others. Secondly, this question is also related to the question of the very method of science. Statistical criteria are used to decide the efficacy of medicines in allopathy. How can this be done in homeopathy and ayuveda when their basis is that of individualisation? Is there a way out? Is the very notion of scientific criteria as used in allopathic science open to question? Is there any alternative scientific method? Can there be? There are a long list of such questions which do not seem to lead us anywhere.

One thing is, however, definite. Research into these systems needs to be given more resources—financial and otherwise. At the same time, unless the efficacy and safety of the non-allopathic medicines have been proved through research, by some intelligible criteria proposed by the authorities in these systems, these drugs should not be allowed to be commercially produced.

Capitalism and Pharmaceuticals

Drug technology was one of the branches of technology, which stagnated for quite sometime even after the advent of the industrial revolution in Europe. The knowledge of human body in health and disease and the development of chemistry was too meagre for quite some time. It is only in monopoly capitalism—the advanced stage of capitalism—that enough resources could be pumped into research in these complicated sciences and it is only then that diagnosis and treatment of diseases could flower into a discipline solidly based on modern science. Modern pharmaceuticals is essentially a product of monopoly capitalism. This same monopoly capitalism has, however, at the same time, become an

obstacle in the path of the full and proper use of modern pharmaceuticals. Monopoly drug companies restrict production and jack-up prices to ensure monopoly profits by using methods characteristic of monopoly capitalism, a lot of irrational and even harmful drugs are pushed onto the consumers. In India and other peripheral countries, this occurs in a very crude manner wherein the market abounds in useless, irrational, harmful products which fetch higher rates of profits. This is at the expense of essential drugs which are at least under some price-control. In the rest, this phenomenon takes place in a more subtle form through a technocratic consumerist ideology of 'pill for every ill'.

The full flowering of the science of pharmaco-therapeutics is also adversely affected by monopoly capitalism. A lot of resources are wasted in inventing 'me-too' drugs which have no significant advantage over the existing ones, but which can be marketed as 'new and better' through aggressive monopolistic marketing techniques. Social resources are also wasted in attempts to prove through 'scientific research', really harmful drugs as safe, or useless drugs as very effective.

Monopoly multinational drug companies represent a classic case of how modern imperialism operates. These monopoly MNCs have on the one hand introduced the fruits of the development of modern science of pharmaco-therapeutics into the third world countries. On the other hand, their monopoly, imperialist interests demand that a part of the surplus value created in the drug industry be pumped off to the imperialist centre; that the drug industry in the peripheral countries be dependent on the imperialist centre so that this sector remains one of the channels of more profitable investments and easier markets. The methods employed to achieve this aim are scandalously bad-production and marketing of the most irrational, irrelevant, and even harmful products at rapaciously high prices through blatantly unethical marketing practices; and the suppression of development of indigenous technology by recourse to 'fair' and foul methods characteristic of monopoly capitalism. The results are more disastrous than they are in the west, since the wastage of and suppression of resources means too much pressure on a weak economy and the impact of cheating and exploitation is much more significant for the poor people who constitute the majority in these peripheral capitalist countries. The contrast between the potentiality of using modern science and technology for the betterment of humankind and the reality of a stunted, distorted development is much more poignantly seen in case of the drug industry in the peripheral capitalist countries.

Contraceptives as a group of drugs need a special mention. The invention of the birth-control pill is regarded by many as one of the important milestones in the path of women's liberation. In reality it is only a defence mechanism for women in the world of patriarchal capitalism in which safe, effective male contraceptives are neither developed nor used adequately. Contraception is considered as the woman's responsibility. The availability of the effective pill in a society wherein women are seen as objects of sexual gratification for men has also meant women's bodies being available 'anytime' without the fear of them getting pregnant. This is convenient for patriarchal men since they can achieve the twin benefit of free sex, and small number of children, without any responsibility or botheration of use of contraceptives.

For the women in peripheral countries and of the ethnic minorities in the imperialist centres, hormonal contraceptives are becoming in addition, a burden on their already poor health. Patently unsafe injectable contraceptives and subdermal implements have given the capitalists, patriarchal state a powerful instrument to enforce its programme of population-control in these countries—at the expense of health of the poor women. Pharmaceuticals which are supposed to enhance feminity are another example of the crude sexism practised by the drug industry.

Pharmaceuticals in Socialism

Human beings would of course continue to fall ill under socialism and communism. The pattern of diseases would, however, be quite different from those in undeveloped capitalism or in monopoly capitalism since this pattern is decided primarily by the nature of social production and the set of relations encompassing it. It would be an idle speculation as to what kind of health problems would exist then and which drugs would be used. All that we can say with certainty is that in socialism and communism, there will be less and less of illnesses and hence less and less necessity of use of drugs in diseases.

In 'existing socialisms' alias state socialist societies (USSR, China, etc.) conditions are, of course, quite removed from this ideal. But the use of pharmaceuticals in these countries is not vitiated by the narrow needs of a profit-hungry drug industry and hence is quite rational. But there are some problems. For example, the widespread use of the injectable contraceptive,-Net-En in People's Republic of China shows that patriarchal relations are present there to quite a substantial extent. In more developed societies—USSR and countries in the eastern block, the disease pattern is not qualitatively different from that in the capitalist west. This, however, does not mean that drugs are overused and misused like in the west since there is no profit-mongering drug industry in these societies. It would be interesting to study the precise nature of use of pharmaceutical in these societies, whether, and to what extent there is any irrationality in the production and use of drugs and why.

Standpoint of Left Movement in India

The Left parties and groups have criticised foreign drug companies as part of their anti-imperialist standpoint. During last six or seven years a lot of concrete work has been done to demonstrate how specifically MNC drug companies exploit and cheat the Indian people and how they thwart the Indian sector. There are, however, two problems in these criticisms—firstly, most of this work has been done by Left intellectuals as part of their research project or by Left activists, as part of the broader 'democratic' science or health-groups to which we belong. This has put certain limitations on the standpoint that is expressed in these analyses and has even put limitations on the very thinking of Left activists. There is a need to a pause and think about these limitations.

In certain academic institutions, financed by the government, there exists a liberalism among decision-makers and hence it is easier to get a research-project to study the impact of MNCs on the Indian drug industry. This liberalism is in tune with the interests of the Indian state; because such

studies fall within the limited anti-imperialist standpoint of the Indian state. The interests of the Indian bourgeoisie demand that MNCs be pressurised into allowing more and more leeway to Indian capital to exploit the Indian people. Studies focussing on the negative role of MNCs are, therefore, even encouraged by the Indian state. Such studies unearth a lot of valuable anti-imperialist material which can be used by people's movements in their thorough-going, revolutionary anti-imperialist struggle.

But a more or less exclusive focus in these studies on the role of MNCs by omitting a critique of the Indian sector is more helpful to the non-revolutionary anti-imperialist struggle of the Indian bourgeoisie. There is comparatively less concrete research in such studies on the anti-people role of Indian companies—and of the public sector. A critique of the Indian sector does not necessarily mean neglecting the distinction between MNCs, Indian private companies—(monopoly and non-monopoly) and the public sector. But a comprehensive critique is perhaps not encouraged. It is no accident that a majority of these studies directly or indirectly financed by the Indian state omit the Indian sector from their critique.

Popular education and propaganda, based on these studies have an ideological, political role of limiting the critique to only the MNCs. The fact that many Left analysts have a limited, anti-imperialist (understood in a narrow sense) political perspective which excludes an important role of a critique of the Indian sector, also helps to sustain this unnecessarily narrow focus. In terms of demands also, the focus of most of Left analysts is limited to the demand for nationalisation of MNCs. In our strategic demands, we should ask for nationalisation without any compensation and with workers' control/democratisation in the nationalised industry. These strategic demands are for the public education of what is possible in the coming stage of the revolution; and hence the fact that the health movement is too weak today, is no argument including this strategic perspective in our study and propaganda.

Criticisms mounted as part of a health or science or consumer group have an advantage in that such criticisms bring into focus the question of irrational and hazardous drugs, misleading propaganda by the drug companies about the efficacy and safety of their drugs and so on. Here again, misdeeds of Indian companies are generally not mentioned. But the demand for banning of irrational and hazardous products, is such that no concession can be given to the Indian sector whose performance on this score has been no better.

As a part of the 'democratic' health/science/consumer movements, Left activists have participated in bringing forward the medical (sometimes feminist) issues and demands. But many such groups do not take a political stand against even imperialism; leave aside Indian capital even though the concrete demands made by such groups and their implications are many times anti-imperialist, anti-capitalist. But a lack of a clear political anti-imperialist, anti-capitalist stand sometimes becomes a hinderance in the progress of analysis in such groups. Part of this problem is due to the fact that people's movements and hence the political culture in such anti-establishment groups has not advanced enough. But part of the problem is also due to the fact that the perspective of the Left activists working in such groups is limited to a purely anti-imperialist standpoint, (understood in a narrow sense). That is why even among Left-journalist, analyses about the drug industry from a comprehensive standpoint are a rarity; most of the writings being from purely anti-MNC viewpoint.

The editorial perspective in RJH is meant to delineate various issues (in a somewhat comprehensive fashion) germane to the theme chosen for the current number of RJH and to make editorial comments on some of them. In the foregoing, I have merged this two-step operation into a single step by making a summary-statement of a certain viewpoint on the three types of major issues which were thought to be central to the theme of this current issues of RJH. There are, of course, viewpoints different from the one outlined above. It is hoped that there will be further discussion and debate on these issues. Obviously, in this number of RJH it has been possible to cover only some of the issues.

Impact of Patent System in India on Indigenous Drug Firms

sudip chaudhuri

A demand is often made by certain quarters to modify the Patents Act of 1970 to make its provisions less restrictive for the patentees. This paper examines the experience under the Patent and Designs Act of 1911 to argue that such a change will go against indigenous efforts to develop processes and manufacture drugs.

THE objective of this article is to briefly relate the experience of the indigenous drug firms with the Patents and Designs Act, 1911 in the context of the Patent Act, 1970 which replaced the former in 1972.

The Patent and Designs Act, 1911 did not categorically state what was patentable.[1] The interpretation followed by the Patent Office was that any new process for manufacturing a drug (whether old or new) was patentable. A new drug was also patentable provided the process of manufacture was described in the patent. The process, however, in such a case was not required to be new.[2] Under the Act of 1911, the indigenous firms have been legally prevented from manufacturing most of the new drugs introduced by the transnational corporations, during the life of the patent secured by the latter, i e, for 16 years, which could be extended to a maximum of another 10 years if the working of the patent had not hitherto been sufficiently remunerative to the patentee.[3] This had been possible because, as N R Ayyangar who was appointed by the Government of India to examine the patent law in India observed, the patentee, while patenting a new drug, could describe all the known and possible porcesses.[4] Actually the TNCs did so, as the experience of the indigenous firms suggests.[5] Even an old process, so specified by the TNCs, could not be used by the indigenous firms for at least 16 years. The latter were also forbidden from processing a patented drug into formulations or importing it.

The TNCs asserted their patent rights to proceed legally against firms which tried to manufacture or import the patented drug. Thus, Hindusthan Antibiotics Ltd (HAL), a public sector firm, e g, claimed that it has developed an indigenous process for manufacturing oxytetracyline Hcl. A plant, in fact, was set up and production began in 1961 without any external technical help. In the same year a TNC, viz, Pfizer too started manufacturing the same drug. HAL had to suspend production as Pfizer took legal action alleging infringement of patent rights.[6] A TNC was importing a drug at Rs 8 per 20 tablets. It sued an indigenous firm, CIPLA, when the latter started importing it at Rs 2 per 40 tablets.[7] Chloramphenicol and metronidazole are among the other drugs for which the TNCs took legal action to prevent the indigenous firms from formulating.[8]

The manufacturing activities of the indigenous firms were restricted to the old drugs or those new drugs for which it could develop new processes of manufacture. We will now discuss two cases which will give an idea about how the TNCs could prevent or delay the use of these new processes, developed through indigenous efforts even when these were not specifically covered in the patents of the TNCs.

Haffkine Institute, a public sector firm, worked out a process for manufacturing tolbutamide from locally available raw materials. A patent was also obtained. Unichem Laboratories, an indigenous firm obtained a licence from it and started manufacturing from 1961. Hoechst, a TNC, however filed a suit claiming that tolbutamide had been manufactured by Unichem on the basis of one of the formulas as mentioned in the former's patent granted earlier in 1956. The judgement of the Bombay High Court delivered in 1968 went in favour of Hoechst.[9] What is important to note here is that Hoechst won the case despite the fact that its patent did not specifically mention Haffkine's process. What clinched the issue was that Hoechst's description was open-ended. One of the claims of Hoechst was, in the interpretation of the judge:

> "Wide enough to cover all methods of eliminating sulphur from thioureas (to manufacture Tolbutamide) whether desulphurisation is effected by means of Hydrogen peroxide (as specifically mentioned by Haffkine) or by the use of any other substance[10] (phrases within brackets ours).

Strange as it may appear, such widely worded claims were permissible under the Act of 1911.

The same patent was also sought to be used for preventing Bengal Chemical and Pharmaceutical Works (BCPW), an indigenous firm, from manufacturing another drug, chlorpropamide. BCPW developed a new process for manufacturing it and obtained a patent in 1959. But in 1961, BCPW received a letter from Hoechst, alleging that the former had infringed upon the latter's patent under which Pfizer had been given a licence to produce it. Denying the allegation, BCPW sought legal action when it continued to receive such threats. Hoechst and Pfizer, on their part, filed a suit in 1962 in the Calcutta High Court against BCPW.[11] This time the judgement went in favour of the indigenous firm. The judge concluded that BCPW's patent was an independent one, not in any way influenced by Hoechst's patent which, in fact, did not relate to manufacture of chlorpropamide at all!

The case is quite revealing so far as the development of indigenous technology and the role of patent legislation are concerned. Hoechst's patent did not refer to any specific drug. It was for the broad group of sulphonyl Ureas. Forty examples were given, but it was claimed that other compounds could be obtained easily from the general formula and chlorpropamide was one of them. Hoechst, however, failed to establish in the court that chlorpropamide could be or had been produced on the basis of the process described in their patent. Even an expert witness appearing for Hoechst admitted that the information disclosed in the patent was not enough to carry out the experiment. But Hoechst could not give specific directions as to how to proceed. One of the specifications, in fact, was found to be chemically incorrect.[12] Significantly, out of the 40 examples provided, none referred to chlorpropamide.

One of the objectives behind the patent laws is to induce the inventors to disclose the inventions (in return for the exclusive right of using the invention for a specified period) so that knowledge may be diffused to facilitate further technological progress. The above-mentioned case illustrates

how the TNCs used the Indian patent law existing then to suppress indigenous growth. It is not only that Hoechst's patent contained inadequate and misleading information which prevents and distorts the diffusion of knowledge. The patent was of a general type, supposed to cover a large and unspecified number of products/processes. Thus, other firms could be threatened with legal consequences even when their product was not at all connected with the patent. All the patent disputes are not fought out in a court of law. A mere threat may be enough deterrant in many cases. Significantly enough, in 1968, before the court hearing started, Hoechst approached BCPW to settle the dispute ouside the court, which however the latter refused.[13]

Compulsory licence: An indigenous firm intending to manufacture a drug is required to obtain a licence from the patentee concerned, if the process of manufacture to be used is covered by the patent. Under the Act of 1911, this was the requirement even if the process in question was well known (but even so had been mentioned in the patent as in the case of new drugs discussed above) or additional technical data were necessary to implement the process and these had been developed by, or obtained from, other sources. Obviously, a patentee may grant a licence voluntarily to anyone on mutually acceptable terms. Compulsory licence is a licence granted by the Controller of Patents (or by the patentee as directed by the Controller) or a non-patentee to use a patent on payment of royalties to the patentee. The Act of 1911 provided for the grant of compulsory licence in case of misuse or abuse of patent rights.[14]

The Patents Enquiry Committee reported in 1950 that the foreign patentees did misuse or abuse their rights, e g, by importing the patented product rather than manufacturing it here, fixing the prices at high levels, not allowing others to manufacture the product even when it was not itself engaged in manufacture.[15] But, as the Committee observed, the provisions regarding compulsory licences were "wholly inadequate to prevent misuse or abuse of patent rights, particularly by foreigners".[16] The Panel on Fine Chemicals, Drugs and Pharmaceuticals, appointed by the government also reported earlier in 1946 that not a single compulsory licence could be obtained because of the wording of the relevant provisions.[17] For example, under Section 22, a compulsory licence could be claimed if "the demand for a patented article is not being met to an adequate extent and on reasonable terms". As the Patents Enquiry Committee commented, the Section unnecessarily also demanded that it has to be proved that as a result any trade or industry had been 'unfairly prejudiced'. Obviously, in practice it appeared very difficult to establish such a link.[18]

The provisions regarding compulsory licence (Sections 22 and 23) were amended in 1950, following the recommendations made by the Patents Enquiry Committee in its interim report submitted in 1949.[19] In 1952, an entirely new Section (23 CC) dealing specifically with drugs (and food, insecticide, germicide, fungicide, surgical or curative devices) was added. Under this section, the Controller of Patents was empowered to grant a compulsory licence to any applicant at any time unless there are 'good reasons' for refusing. The foreign patentees, however, were still in a position to effectively prevent or delay the use of compulsory licence.

The Haffkine Institute, e g, applied for a complusory licence, but the foreign patentee offered to give the licence voluntarily on the basis of royalties to be fixed through negotiations. They demanded an absurdly high rate of royalty of 25 per cent. It took more than four years to reduce it to 10 per cent, which however was still higher than the limit of 5 per cent stipulated by the Reserve Bank of India. By that time the Haffkine Institute decided to abandon the scheme.[21] Again, another indigenous firm Neo Pharma Industries entered into a technical collaboration agreement with an Italian firm for the technology to manufacture chloramphenicol.

A licence was sought from Parke Davis, which held the relevant patent in India. But whereas the subsidiary company in India pointed out that the matter was beyond its jurisdiction, the parent company in the USA insisted that Neo Pharma should first discuss with the local company. It took more than two years to decide as to who would negotiate. At last when the negotiations started with the parent company, they did not formally refuse to grant a licence but simply sat over the proposal. Finally, when a compulsory licence was sought for and was granted, Parke Davis went to the court and obtained a stay order.[22]

In fact, going to the court is a simple device the foreign patentees could employ. Even if ultimately the judgement goes against the patentee, the applicant would normally be prevented from using the compulsory licence during the period of the court case. The longer the time taken to settle a case, the smaller will be the relative benefit to the applicant for compulsory licence, because in any case after the expiry of the patent (normally 16 years) anybody was free to use the patent. The hazards of obtaining a compulsory licence, which include legal battles, perhaps explain why so few applications for compulsory licence were made under Section 23 CC. Till 1972, i e, when a new Act came into force, there were only five applications for compulsory licence, made by Hindustan Antibiotics Ltd (in 1959), Alembic Chemical Works (1963), Dey's Medical Stores (Manufacturing) (1960), Raptakos Brett and Co (1957) and Neo Pharma Industries (1961).[23] The applications were ultimately withdrawn in the first two cases. Compulsory licence was refused by the Controller of Patents in the third case.[24] The controller granted compulsory licences in the last two cases.

Patent System under Act of 1970

An important feature of the new Act, 1970[25] is the special provisions regarding drugs and a few other products. The life of the drug (and food) patents has been reduced from at least 16 years in the previous Act to five years from the date of sealing.,[26] or seven years from the date of filing of complete specifications, whichever is shorter (sections 45 and 53), i e, for a maximum period of seven years. For other patents, the duration is 14 years. The new Act categorically states that drugs (and food and those manufactured by chemical processes) can now be patented only for a new method or process of manufacture, not for the products as such (section 5). Hence in contrast to the previous situation, the indigenous firms can manufacture new drugs by old processes without violating the Act. Obviously, as before it can continue to manufacture old drugs. Even in cases where new drugs cannot be manufactured by known processes, and so a new process is required, the indigenous firms are expected

to face less restrictions in developing such new processes. This is because the firm discovering/inventing a drug can no longer patent all the processes known to it even if these are new. For a particular drug, only one method or process—the best known to the applicant—can be patented (Sections 5 and 10).[27]

Under Section 87 of the Patents Act, 1970, every patent relating to processes for manufacturing drugs (or food or chemical substances) has to be endorsed with the words "Licences of right" after three years of the date of sealing. This implies that anyone is automatically entitled to a licence from the patentee for using the patent on payment of royalties, the maximum rate being fixed at four per cent of the ex-factory sales (Section 88). Even before expiry of three years from the date of sealing, the controller is empowered to grant a compulsory licence (and fix the rate of royalties) if "it is necessary or expedient in the public interest" (Section 97). There is also a special provision in the Act of 1970 regarding the use of patents by the government. Any time, a patent may be used for official purposes, including those of public undertakings. The maximum royalty payable for such a use, in case of drugs (and food) has been fixed at 4 per cent of the ex-factory sales (Sections 99 and 100).

It must be pointed out, however, that the actual use of a patent by a non-patentee still remains hazardous. For example, under Section 87, as mentioned above, while the right to obtain a licence automatically accrues after three years from the date of sealing of a patent, it cannot actually be used till the royalties are fixed either mutually or at the intervention of the controller. As before, the patentees can continue to prevent or delay the use of their patents by others by refusing to negotiate and then proceeding to the court in case of any intervening action by the controller. This has, in fact, happened in the case of each of the applications made to the controller till now by three firms for fixation of royalties. Incidentally, all these cases relate to products other than drugs. In the case of the application made in March 1976 by Catalyst and Chemical India (West Asia), the controller fixed the rate of royalty tentatively as per Section 88(4). The patentee (ICI), however, went to the court and by the time the case came up for final hearing (July 1977) the patent was about to expire (in August 1977). In the remaining two cases, as the patentees approached the court, interim injunction was granted and the Patent Office was directed not to proceed with the applications of Titanium Equipment and Anode Manufacturing Co and Coromandel Indag Products made in September 1980 and July 1981 respectively. The two patents in which Titanium was interested expired in February 1983 while the court case was still pending. Regarding Coromandel, too, while the case is yet to be settled, one of the patents has already expired in March 1982, while the other is due to expire in February 1986.[28]

Despite such hazards, the Patents Act, 1970 appears, on the whole, to be an improvement from the point of view of the development of indigenous science and technology, compared to the previous situation. A demand is often made by certain quarters to modify the present Act and make the provisions less restrictive for the patentees. If the experience under the Act of 1911 is any guide, then such a change will go against the indigenous efforts to develop processes and manufacturing drugs.

Responsibility of Industry, Doctors and Government

amitava guha

The proliferation of irrational and dangerous drugs in India has generated a well-informed and dynamic drug consumer's movement. Of the several issues that it has taken up the issue of banning high dose oestrogen progesterone drugs illustrates best its capability. On the other hand, the issue has also revealed inefficiency of the drug control authorities, their inability to implement the rules in the book designed to protect the consumer.

This inefficiency on the part of government institutions is compounded by their close collusion with the drug inaustry. The medical profession has also played a crucial role in opposing the ban of these drugs. The article highlights the unethical practices and actions of the different sections who have been involved in pressing for the continued marketing of high dose EP drugs.

IN 1982, the Indian Council of Medical Research recommended:

> "Fixed dose combination of oestrogens and progesterone may be totally banned in the country, even for the treatment of secondary amenorrhoea as other substitute are available in the market for management of secondary amenorrhoea"

Based on this recommendation, the ministry of health and family welfare banned HDEP in June 1982. Today five and half years after, the drug is freely available in India! The industry, medical profession, courts of law even the government departments played their role in undoing the govt's ban order.

For the first time in India the question of banning of a drug is being discussed and debated; consequently it has exposed the low level of ethics followed by the people involved in the medico-technical establishment.

It must be pointed out that the issue of harmful effect of a drug and therefore, its banning had never been raised by the medical profession. Even the issue of harmful effect of 'thalidomide' was taken up by the journalists and the ripple created in the so-called 'lay press' raised a wave which not only washed away any effort to defend the crime made by Gruanthal (its manufacturer) but exposed the menace of the industry in collusion with certain famous opinion maker medical personnels. In India similarly nothing is being said or no action had been taken by the famous doctors or opinion makers against the horde of drugs banned in developed countries but freely and legally available in India. It is again the 'lay press' *Onlooker* which raised the issue through the write up—"Pregnancy Test Drugs can Detorm Babies—Ban them". The issue, thereafter was widely taken up by the press and excepting one or two write ups till date none of them had spoken against the ban of HDPE.

Role of Industry

Harmful effect of the drug on pregnant women was detected as back as 1967 for. Pioneering task in this area had been taken by Dr. Isabel Gal. She writes:

> "The unfavourable effect of synthetic sex hormones on animal reproduction was known long before the introduction of HPT products in 1958. Despite this the manufacturers recommended HPT products as a safe and reliable method of pregnancy diagnosis and gave assurance that it does not interfere with the physiological course of pregnancy"

Following the reports of adverse drug reaction with HDEP, Rousel in 1970, Schering in 1971 and Organon in 1970 did not refer to use of the drug for pregnancy test in UK. The government of India issued order that this drug should not be used for pregnancy testing and the order be printed on the labels of the drugs marketed. The drug was established in India as an abortificient. It was promoted widely for inducing abortion. Even after the said order issued by the government, the companies promoted the drug through marketing staff as an abortificient.

Immediately after the ban order was issed, Organon India Ltd., (now Infar) placed a writ petition in Calcutta High Court and was interested to see that the writ was not contested by the Drug Controller of India during its hearing. It happened exactly as desired by the company and the case was heard and injunction was passed exparte against the ban order. It is interesting to note that neither M/s. Organon nor M/s. Unichem and M/s. Nicholas contested the finding of ICMR on the potential hazard of the drug but simply challenged that the ban order was not issued in accordance with the provisions of law. It was submitted that Sec. 18 of Drugs and Cosmetics Act allows the state govts only to ban a drug after issuing official Gazette Notification. That too the Act only provides banning of misbranded, sub-standard or adulterated drugs. This was an eye opener for the legislators, who after much shouting from the consumers and by some Members of the Parliament amended the law later giving the same power to the Central Govt also. Even now the question remains that HDPE or any harmful drug, if banned, should be done according to which law?

The industry did a lot to utilise medical profession in their favour. In the submission to the Supreme Court and high courts, the company placed letters written by a number of general practitioners and gynaecologists stating that HDEP should not be banned. In reality this was again done with the help of the marketing staff who went to the doctors with the draft of such letters and requested them to write according to the draft, a letter on their own letterheads. Therefore, it was found that the letters are not only the matically similar but, so is the language and text of the letters. In some cases the marketing staff of the companies wrote the letters on the doctor's letter pad and asked the doctors to sign them. The text of these letters more or less read:

> "I support the order of the government in banning the use of high dose E. P. Drugs in pregnancy testing.
>
> The drug is highly needed for treating secondary amenorrhoea, dysfunctional uterine bleeding, endometriosis and dysmenorrhoea. I have used this drug for a long time and never seen any adverse effect. I recommend that this drug should not be banned".

The industry made another attempt to mislead the courts on the information regarding the status of the drugs in different countries. Organon (I) Ltd stated that

> "It's not a fact that many countries have banned these preparations. These preparations are available in countries like UK, West Germany, France, most of the Western European countries and many South West Asian and African countries" (Infar, 1987).

One can easily find out how far this is a fact. Table 1 will clarify the position (UN List, 1986).

Infar (I) Ltd had no reply when asked at the public hearing why HDEP was not allowed to be marketed in their

parent country, Netherlands. Similarly, the company could not say why the drug was not allowed to be introduced in many other developed countries. The company's honesty was again questioned when Hermann Schulte-Sasse of the Institute for Clinical Pharmacology, Hamburg confirmed that.

"Two German pharmaceuticals marketed such drugs in Germany but withdrew them at the end of 1979".

Was the company confident that Indian consumers did not have any access to information from 'civilised European countries'? In fact Dr N N Roy Chowdhury, the president of Federation of Obstetrics and Gynaecological Societies of India (FOGSI) wrote to DCI to the same tune of Infar Co that the drug was available in most of the developed countries. He had also submitted a list although he did not care to mention any reference. From this list it appears that 'Shering' (he does not know that the real name of the company is Schering Aktiengesellschaft) market HDEP in West Germany, UK, Turkey, Japan, Argentina, Mexico, Belgium, Denmark, Australia. The drug is not enlisted in the 'Red List' (Rote Liste) 1984, 1985, 1986, 1987, a list of drugs approved by the government of FRG. Corroborative statement from Schering issued by Dr H Richter informs that only one brand of HDEP was marketed by them in third world countries that two had been withdrawn from October, 1986.

In the absence of any system of dissemination of unbiased information to the medical profession, the industry takes the fullest advantage to misinform the profession to mislead them with the help of their own tailored and distorted facts. As regards high dose EP drugs, the industry had taken the fullest advantage of this situation. The Voluntary Code of Marketing Practices adopted by International Federation of Pharmaceutical Manufacturers Association (IFPMA) suggests that

> "Scientific and technical information shall fully disclose the properties of pharmaceutical products as approved in the country in question based on current scientific information...
>
> "Information on Pharmaceutical Products should be accurate, fair and objective, and presented in such a way as to confirm not only to legal requirements but also to ethical standards and standard of good taste." (IFPMA)

Classical example can be sited from the promotional literatures of Infar(I) Ltd as to how they have violated all such codes of ethics. Even the Guidelines of Introduction of New Drugs by Government of India say that "the product monograph should comprise the full prescribing information necessary to enable a physician to use the drug properly. It should include description, actions, indications, dosage, precautions, warnings, and adverse reactions."

A product monograph of Orgalutin, a high dose of EP used to promote the drug to the doctors is captioned as 'A Woman's Strength Is a Woman's Weakness'.

Table 1: Status of EP Drugs Worldwide

Countries	Status	Year
1. Norway	Withdrawn	1970
2. Sweden	Banned	1970
3. Finland	Banned	1971
4. Federal Republic of Germany	Withdrawn	1979
5. USA	Banned	1975
6. UK	Withdrawn	1977
7. Australia	Withdrawn	1978
8. Austria	Withdrawn	1978
9. Belgium	Withdrawn	1978
10. Italy	Withdrawn	1978
11. Greece	Withdrawn	1980
12. New Zealand	Withdrawn	
13. Denmark	Banned	1974
14. Bangladesh	Banned	1982
15. Venezuela	Banned	1975

On page three of the monograph to emphasise that the drug is 'safe for the patients' the following lines are mentioned quoting a write up of two doctors Dr Choudhury and Dr Mitra that with the use of the drug there was—

> "No alteration in blood pressure.
> No alteration in blood-sugar level.
> No hepato-toxic effect observed".

The said monograph had given indications of composition and dosage only but nothing was mentioned about precautions, warnings and adverse reactions.

If the warnings and precautions circulated by the company a few years back are consulted, one can find the following facts in the Therapeutic Index of the company and judge how safe the product could be,

> "Since such preparations may cause an increase in blood pressure in predisposed women, this should be checked regularly. In case of serious hypertension the use of the preparation should be stopped immediately."
> "Since the glucose tolerance may diminish during the use of oestrogen/progestogen preparation, diabetic patients should be kept under strict control."
> "Hepatic adenomas have been reported in women on oestrogen-progestogen combinations."

This gives us an opportunity to question the standard of ethics maintained by the company and of the two doctors who had shamelessly concealed the facts.

It is also interesting to note that the manufacturers of HDEP were really frightened of the ban order issued by the governments. In the Therapeutic Index printed by Infar(I) Ltd at the time the ban order was issued, the company deleted all HDEP drugs namely, Menstrogen, Menstrogen Forte and Orgalutin. But their effort to promote the drug in the market remained unhindered. The company has never forgotten to mention these drugs in their price list!

Role of Statutes

Important statute applicable to import, manufacturing, etc of any drug is the Drugs and Cosmetics Act, 1940 and the Drugs and Cosmetics Rules, 1945. This is not only ancient but highly inadequate also. Although it is a central statute but it has given authority to the State Drug Controllers for approval of a drug for registration and sale. Because of such inadequacy of law, the Central Drug Standard Control Organisation has prepared 'Guidelines on Introduction of New Drugs'. We shall see how even the scanty restrictions under the said Acts and Guidelines have been violated by the industry.

Organon (India) Ltd, now Infar (India) Ltd had introduced the HDEP about 20 years before. Earlier, these hormones had been marketed separately as single ingredients or in combination as oral contraceptives. The drug was imported and the definition of a 'New Drug' under Rule 30A of the Drugs and Cosmetics Rules (DCR) says:

> "The importer of a new drug when applying for permission shall produce before the licensiong authority all documentary and other evidences, relating to its standards of quality, purity and strength and such other information as may be required by the licensing authority including the results of therapeutic trials carried out with it." (Drugs and Cosmetics Rules)

At the time of introduction of the drug it could be defined as a Fixed Dose Combination (FDC) of the third group according to the Guidelines on Introduction of New Drugs. This Guideline requires:

> "(c) the third group of FDC includes those which are already marketed, but in which it is proposed either to change the ratio of active ingredients or to make a new therapeutic claim.
> For such FDC, the appropriate rationale should be submitted to obtain a permission for clinical trials and reports of trial should be

submitted to obtain marketing permission."

The clinical trials required to be carried out in India before a new FDC is approved for marketing depend on the status of the drug in other countries. If the drug is approved/ marketed, phase III trial is usually required to be conducted in India. If it is not approved/marketed, trials are generally allowed to be initiated at one phase earlier to the phase of trials made in other countries.

On going through the records one can easily find out that the company never obtained any permission to initiate clinical trials in India as required by Drugs & Cosmetics Rules (through form 11 and form 12) for a test licence. No protocols for any trials were ever submitted by the company—this is required according to the Guidelines for Introduction of New Drugs. No case report forms were ever submitted.

As required in the Appendix III of the said guidelines the following reports on the studies are to be submitted by the company. (1) Human/clinical pharmacology (2) Exploratory Trials. (3) Confirmatory Trials. This was never done. Neither the company nor the Director of Drugs Control, Government of West Bengal, who allowed the company to sell the drugs in India can produce the following records relating to trials supposed to have been conducted by the company and approved by the government authority.

Title of the Trial

Name of Investigator and Institution

Objective of Tribals

Design of Study: open, single-blind, or double blind, non-comparative or comparative, parallel group or cross over.

Number of patients, with criteria for selection and exclusion, whether written informed consent was taken.

Treatments given: drugs and dosage forms, dosage regiments method of allocation of patients to the treatment;

Observations made before, during, and at the end of treatment, for efficacy and safety, with methods used.

Results: exclusions and dropouts, if any, with reasons, description of patients, with initial comparability of groups where appropriate, clinical and laboratory observations on efficacy and safety, adverse drug reactions.

Discussion of results: relevance to objectives, correlation with other report/data, if any guideance for further study if necessary.

Summary and conclusions.

In order to maintain a minimum standard of ethics, trials should be conducted with any drugs prior to their introduction in the country. For the purpos, 'licence for examination, test or analysis' has to be procured under Rule 21(c) which was never done by Infar in this case. While applying for manufacture of 'New Drugs' as per Rule 75-B of the DCR one needs to supply "informations as may be required including the results of therapeutic trials carried out with it" (sub sec ii). This was never done either by the manufacturers of HDEP.

It is striking to note that a controversial drug was introduced in our country at the time when enough controversy was raised elsewhere. The manufacturers never cared to conduct any trials in India. They were not only given licence to manufacture such a drug but it was periodically renewed by the drug control authority.

The guidelines for the introduction of new drugs per sec 9.2 under the title 'Regulatory status in other countries' state. "It is important to state if any restriction have been placed on the use of the drug in any other country, e g, dosage limits, exclusion of certain age groups, warning about adverse drug reaction".

This was not done at any time—either at the time of introduction of the drug nor any time thereafter by Infar. On the contrary, as discussed before, the manufacturers have attempted to misguide authorities with false information that the drug is in use in many developed countries.

The guidelines also require (sec 9.3) a 'Free sale Certificate from the Country of Origin'. It would be almost impossible for Infar to submit such a 'free sale certificate' as it was never allowed to be manufactured and marketed in Netherlands, their country of origin.

Not only question of ethics but the failure of the regulatory authorities and the lacuna in the laws are exposed when we consider that the manufacturers have not cared to submit to the minimum requirements of law and the government guidelines and have developed a large market of Rs 6.18 crore yearly.

Role of Doctors and Professional Bodies

A famous gyaenocologist C S Dawn has written in his widely used text book.

> Secondary amenorrhoea has had spontaneous cure rate in more than 50% cases where any treatment becomes empirical. New therapies of pituitary gonadotropin, clomiphene and bromocryptine showed promising results in the treatment of selected cases where these are indicated. Longer the secondary amaneorrhoea persists poorer becomes the prognosis.

He, as a professor, never vouched for the use of HDEP in secondary amenorrhoea in the classrooms and thus hid his other face. For, as a member of the Federation of Obstetrics and Gynaecological Societies of India (FOGSI) he says exactly the opposite. He attended the public hearings held at Madras, Delhi and Calcutta just to say that as an eminent teacher and famous gynaecologist he had never seen any adverse reaction with HDEP, and the drug was very much needed for treating secondary ameneorrhoea.

His notoriety had not stopped here. After the Delhi public hearing, he had submitted a study report on May 10, 1987 of a purported trial as a chairman of the family welfare committee of FOGSI. The report was titled as 'Use of Common Drugs in Pregnancy—Indian Experience'. It is only two-page monograph but the dimension of the study is enormous as the first paragraph of this report says:

> "An all-India multicentric study was conducted during 1982 and 1983 by the Food, Drugs and Medicosurgical Committee of FOGSI by the author as the chairman of the committee. Fourteen teaching and rural centres participated in this study. Statistically controlled protocol was prepared in consultations with Department of Hygiene and Public Health, Calcutta. The protocol covers 78 factors".

No further methodology and materials used in the study was mentioned. The result was:

> "There were 245 congenitally malformed newborns in this study. The incidence of congenitally malformed newborns at various centres varied from 2 to 10 per 1000 births".

The report never mentioned directly as to *how many pregnant women were covered in the study.* If the average incidence of malformation of newborn babies are considered, according to the study, say five per 1000 and a total number of malformed newborn babies reportedly were 245 then we arrive at the fact that in order to get such result, the trial covered 49,000 pregnant women. That such a phenomenally high number of patients were covered in only one year from "14 teaching and rural centres" is noteworthy as this type of trial is impossible even in developed countries.

In the Calcutta public hearing Dr. Dawn was asked that in order to prove that his trial was not fake, he should submit papers relating to the ten protocols as required by the government. Dawn is yet to prove that it is not fake. Obviously the sole objective of producing such a report, which has never been published in any professional journal was to prove that no congenital malformation could be found with the use of hormonal drugs during pregnancy. When the government had banned the use of HDEP during pregnancy and the manufacturers have accepted it, the eminent doctors like Dawn, C L Jhaveri, P K Khan, Sharma are all rejecting it.

Dr. Sharma of Delhi and Khan of Calcutta had without any hesitation said at the public hearings that they would continue to use HDEP for pregnancy testing. We are yet to see the Medical Council of India react to such violations by cancelling the registration of these doctors.

Dr. Jhaveri of Bombay, seniormost and famous gyaenocologist and many times president of FOGSI went even further that estoprogin (HDEP) drug came as a blessing. It had helped—in the second world war women who had been assaulted by the soldiers had used HDEP drugs to abort unwanted feluses! He stated in the Delhi and Bombay hearings that in his 40 years' of gynaecological practice he had used the drugs *for inducing abortion* and had not found a single case of malformation of babies. His statements were recorded by the Drug Controller of India during the public hearings.

One may conclude that Jhaveri had committed punishable offences in two cases. First, he had practiced MTP when it was not legalised. Second, that he had violated the government order in using the drug on pregnant women. We are yet to see that DCI take any action against Jhaveri. This septugenarian doctor was so loyal to the arguments put by the industry that he rushed to the dias at the Bombay hearing to assault one speaker who was dissecting a point of law placed by the industry.

A good number of famous gynaecologists have attend almost all the public hearings leaving their generally over crowded chambers and have said the same things repeatedly. They had not cared to place any pharmacological and clinical evidence in support of their statement that the drug is safe and necessary.

In the Delhi and Calcutta hearing N N Roy Chowdhury, president of FOGSI stated that the Federation had unanimously adopted a resolution that the government should not ban HDEP as they were safe and needed to treat secondary amenorrhoea, dysfunctional uterine bleeding, endometriosis, menopausal symptoms, etc. and there was no substitute for this drug. This statement was challenged by a professor of gynaecology at Calcutta who as a member of FOGSI wanted to know where and when such 'unanimous' resolution was taken. He also produced a statement by Dr J Mitra, Honorary Joint Secretary of FOGSI which states

> "I am of opinion that high dose combination of oestrogen-progesterone should not be used during pregnancy.
>
> I also feel that it is not essential to use this high dose combination for treating gynaecological condition like dysfunctional uterine bleeding, menopausal syndrome, etc. These combinations should not be used indiscriminately as there are potential hazards."

Roy Chowdhury could not provide any proof to substantiate his statement which was openly challenged.

Another instance of violation of minimum standards of ethics can be cited with reference to the activities of P K Banerjee, Honorary Treasurer of the Indian Medical Association. There are complaints by his professional colleagues that he is an obedient supporter of Infar (India) and defended the company's interest in using anabolic sterioid for promoting growth in children. Banerjee wrote a letter to DCI dated April 6, 1987 in the capacity of honorary treasurer, IMA stating that the drug is much needed and harmless. On inquiry, it was found that he had misused the good name of the IMA. As the President of IMA stated that

> I would like to mention that the letter issued by Dr Banerjee is his own view and he is not authorised to communicate the views of IMA. It is unfortunate that he has used IMA stationary for expressing his personal views".

It is necessary to mention here the role of the two doctors who were involved with banning the drug—P Das Gupta, Deputy Drug Controller and P K Dutta of World Health Organisation. The Deputy DCI had no scruples about favouring the industry openly. He tried to dilute the issue.

The Supreme Court had clearly asked the DCI to conduct public hearings on banning of high dose combinations of E P drugs. The Deputy DCI, at the Calcutta hearing, attempted quite something else. He stated that the question of banning HDEP should not be taken as an ego fight. Although the Drugs Controller's office had once banned it, it did not mean that they should stick to such decision for- ever. He also appealed to the gynaecologists that they should come forward and suggest a 'cut off' dose for estrogen-progestogen combinations. He wanted to confuse the issue on the question of high dose and low dose EP. He wrote letters without the knowledge of DCI to FOGSI and Indian Associations of Fertility and Sterility asking them to give their views on a questionnaire on estrogen progestogen combinations, dated March 23, 1987. He carefully dropped words 'high dose' in the questionnaire. The questions are tailored in the following way which is suggestive of the desired answers.

> 1. Whether fixed dose oestrogen and progestogen is necessary i. the management of secondary amenorrhoea?
>
> 2. What are the possible side effects of fixed dose oestrogen and progestogen combination?
>
> 3. Do you feel that with a suitable cautionary label the use of fixed dose of oestrogen and progestogen combination in pregnancy be prevented?
>
> 4. Whether fixed dose oestrogen and progestogen combinations are marketed in other countries?
>
> 5. Whether fixed dose oestrogen and progestogen drugs should be banned?
>
> 6. Do you have any other suggestions on this issue?"

Nowhere in the above questionnaire had Das Gupta mentioned '*high dose* estrogen and progestogen'. It can be noted that oral contraceptives are also fixed dose oestrogen and progestogen combination. The president of these two organisations C L Jhaveri and N N Roy Chowdhury made full use of such questionnaires and pumped the arguments of the industry in their reply which was considered by Das Gupta as an important document at the public hearing held at Bombay where Prem K Gupta, DCI who was absent at the Calcutta public hearing said that this was done without his knowledge and offered an apology for the action of the Deputy DCI.

At the Calcutta hearing Das Gupta was openly supporting the manufacturers of HDEP. He, along with Dr P K Dutta helped the management of Infar to create a stir at the public hearing and cancelled the hearing with a plea that they may be physically assaulted when there was no valid reasons to do so.

It is necessary to mention the role of other doctors and professional organisations. The reactions of famous gynaecologists and pharmacologists of UK on the need of HDEP were different. Some of these doctors are members of the Committee on Safety of Medicines. Some of the responses are as follows;

> 1. "I feel strongly that there is *no justification* for the use of these drugs in amenorrhoea, menstrual irregularities and other "gynaecological disorders". Amenorrhoea and menstrual irregularities require investigation and specific causes identified and, if necessary, treated. If menstrual regulation is required in patients who have no periods and who have irregular (and perhaps heavy and painful) period then the treatment of choice is either the conventional *low dose* estrogen-progesterone oral contraceptive pill, or progestogen alone.
>
> I think it would be irresponsible and dangerous to encourage the use of high dose estrogen-progestogen combinations in management of these gynaecological symptoms". (Dr. Stephen Franks, Reproductive Endocrinology; St Mary's Medical School, London).
>
> 2. "I was alarmed and disturbed to learn that high dose combinations of oestrogen and progestogens are still marketed, and used in the Indian sub-continent. I understood that steps had been taken in 1983, to withdraw these products and I find it extraordinary that four

years later it is still possible to promote, prescribe and purchase such medicines.

They are associated with significant risks to the factus, if administered during pregnancy. The Committee on Safety of Medicines (of which I am a member) issued warnings to all doctors about these hazards in 1975 and 1977. The British Medical Journal drew attention to the problem in an editorial in 1974. As a result of these publications, and of professional opinion, pharmaceutical companies in the UK voluntarily withdrew their products containing high dose oestrogen and progestogen from the market.' (M D Rawlins, Professar of Pharmacology, University of Newcastle upon Tyne).

3. "I find that I am in complete agreement with the opinions expressed by Dr Steven Franks and Professor Rawlins and I have no reason to change my own views, as expressed therein. Perhaps the only thing I could add is that now, with four years experience as a member of the United Kingdom's Committee on Safety of Medicines, I'd like to emphasise Professor Rawlin's point—that is, that these drugs would be unacceptable in the United Kingdom, that our attitude is that the obligation is on the pharmaceutical company to prove quality, safety and efficacy of preparation and not on the drug regulatory agency to prove the converse and that, while those drugs are certainly not banned in the United Kingdom, were any attempt to be made to introduce them I have very little doubt they would fail to secure a licence". (Dr H S Jacobs, professor of Reproductive Endocrinology, The Middlesex Hospital Medical School and University College, London).

The Public Hearings

Thus, famous professors of the medical institutions did not hide their surprise and disgust at the use of the drug and role of government regulatory authority, nor did a large number of the specialists in Calcutta and Bombay hearing. The DCI initially decided to close the public hearing after Delhi. About 150 doctors including professors of gynaecology and pharmacology wrote to the DCI to hold the hearing at Calcutta as well. Initially there was no respond from the DCI. This gave raise to such a reaction that at the instance of the Association of Health Service Doctors, West Bengal about 200 doctors assembled in a convention condemned the activities of the DCI and resolved to start a campaign against the drug manufacturer and the government of India for not banning the hazardous drugs. This compelled the DCI to announce public hearings at Calcutta and Bombay four months after the Delhi hearing.

During the Calcutta hearing, a large mass action for banning the drug took place. For the first time the trade unions, doctors, consumers and health activists demonstrated before a drug company and condemned them for production of banned drugs. It was encouraging to see that for the first time, famous doctors who had been vouching for the industry were challenged by other well-known professors, gynaecologists, pharmacologists.

At the Bombay hearing it was also quite amazing to see that when Jhaveri said, that he would give an award to anyone who could place any evidence of foetal malformation by HDEP, it was accepted by other group of doctors. The real drama took place at the Bombay public hearing when this group of doctors placed a little girl and her mother as evidence of the foetal abnormality and placed a letter which had congratulated them for their effort to detect such drug induced malformation of the baby. The author of the letter was none other than Dr. Jhaveri himself.

Role of People

Long back, after the publication of the write up in *Onlooker*, certain health activists tried to take up the issue but it could not spread. Even when the issue reached the Supreme Court, Vincent Panikulangara a lawyer from Kerala had to fight for a ban quite alone.

In Madras, Delhi and Calcutta hearing some people appeared as 'consumer activists'. Their expressed concern was more on 'illegal' and 'unjust' blames being attributed to the industry than on the harm to consumers. They forgot that this hearing was most important because for the first time merits and demerits of a drug were being publicly heard. They also forgot that their counterparts in developed countries have forced the companies to obey a minimum code of conduct and Infar was admonished by the International Federation of Pharmaceutical Manufacturers Association for violation of its voluntary code however biased, weak and ineffective that may be.

It has also true that the trade unions had palyed different role in different places. While at Madras and Delhi there was no scope for their intervention they responded remarkably positively at Calcutta. Unions of medical representatives, the Federation of Medical and Sales Representatives Associations of India (FMRAI) and the Organon(I) Ltd Workers Union organised a demonstration in front of the gate of the Infar factory. The workers attended it and the president of their union announced that if the company failed to convince them that the drug cannot cause any harm to the people they would refuse to produce it. The representatives of FMRAI appeared before the public hearing and narrated how they were being directed by their employers to misguide the medical profession with partially or totally false information. They also exposed how the Infar and Unichem had been entertaining and spending money for providing travelling expenses of a particular group of famous doctors who had been appearing before the public hearing on repeated occasions. They also stated that the drug was sold by the companies without any promotional effort. The companies are manufacturing the drug and through their distributioin channel it is reaching the outlets where it is automatically sold. The margin of profit in this drug is among the highest.

In contrast to this, the role of the Shiv Sena Union of Unichem at their Bombay factory not only favoured the industry but workers openly threatened the audience that if anyone spoke against their management, they would be forced to take drastic actions. There was a large number of Shiv Sena activists at the Bombay hearing who had been booing and shouting at the women's group whenever they expressed their concern which was often tinged with emotion. This shows the difference in level of consciousness among the workers of the two places.

There was remarkable response from womens groups. In 1979 some women's groups of northern and western India took up the issue. The issue of banning a drug cannot be solely seen in terms of exploitation of female by male. It is also not because Dr Isabel Gal was a women that she first explored the hazards of the drug. The question of banning a drug concerns the profit motive of industry and the low standards of ethics of some eminent opinion-makers of the medical profession in India. During the public hearings. Most of the women's groups identified the crux of the issue—that the existing condition in our country is conducive to industry-government clique. Some of them asked a pertinent question: Why had the court not first banned the drug in the interim which is said to be causing danger. Who would be held responsible for any damages which are being caused even now (if at all) the drug is officially banned in future? They have also declared that they would file litigations against any future malformation of newborns and would ask for compensations from the Drugs Controller and the industry. However the question remains that when there is dearth of ethics among all levels of the decision/opinion-making in the establishment can the judiciary remain un affected?

[While preparing this paper help had been sought from the excellent compilation of documents and different monographs prepared by Mira Shiva, Coordinator, All India Drug Action Network.]

The Socio-Political Dimension

imrana qadeer

The EP drugs issue has brought into focus the sickness not only of the legal system, but of the medical system as well. How is it that we are fighting a case which should not have arisen at all in a sane society? In reality the very need for pregnancy testing is rooted in the maladies in the social situation and the inadequacies of the health system. Thus the movement against EP drugs and other such technologies must be woven into the wider political movement against a system which breeds, and protects such oppressive developments.

THE addition of high dose oesterogen and progesterone combinations to the long list of oppressive technologies for women is not recent. These drugs have been freely sold in the market for some time now, even though scientifically speaking—their use is not indicated. Its use however, has created such havoc that the victims, that is some of the women, could not bear it any longer. Their protests led to the banning of the drug. The ICMR had already recommended its ban as a drug for pregnancy testing and the court passed a judgment banning its sale. These steps by the authorities were brought to naught by the companies which used the loopholes in the legal system. They obtained the right to continue their business not because they proved the drug safe but because they argued that the Drugs and Cosmetics Act had no provisions to ban a drug (however lethal it might be)! Their victory over the petitioners (women), the referral of the case to the Drug Controller of India and the public hearings in the major cities have revealed a lot more about the sicknesses of not only the legal system but also the medical system.

This compels one to ask, how is it that we are fighting a case which should not have been there at all in a sane society? How is it that while life saving drugs are scarce, dangerous drugs are so easily available over the counter? How is it that the majority of those who flaunt the Hippocratic oath as a mark of their superior professional ethics, preferred to stay out of the controversy when the health of their clients was being jeopardised? How is it that for the sake of so called scientific advancement and the doctors' right to chose treatment for their patients, needy people are treated as guinea pigs whose lives seem to be of very little value?

When we ask ourselves these questions, it is not difficult to see that the issue is not confined to EP drugs but relates to the very nature of technology which is being propagated today in the area of population control. To give it scientific neutrality this area of research is called 'reproductive biology' and constitutes a part of the larger field of 'biotechnologies', all meant to intervene in natural biological and not social processes. They do however, become tools in the hands of some and thereby influence the social process in a way desired by only those sections who are in control. One, therefore, has to ask a very basic question, do the majority really need these technologies? And if they do, what should be the limits of their use?

In this age of modernity and high technology, such questions might sound backward, even anti-technology, but they are neither. Let us ask ourselves why do we need pregnancy tests? The reasons are simple enough.

1. These couples/women for some reason either do not want to have a baby or on medical grounds need to know their status so that adequate care may be given to them as in the case of pregnancy in diabetic or heart patients or in case of high risk mothers with high probability of congenitally malformed or diseased foetus.

2. Apart from these medical reason yet another reason for pregnancy testing is to make a timely choice for abortion if the sex of the baby is undesirable.

If the right of a women to avoid a pregnancy is accepted, then, why is it that despite years of research, in reproductive biology and contraceptive technology, despite millions of dollars that have gone into this research, we still do not have a contraceptive which is safe for the user, sure and cheap? The researchers have in fact sacrificed safety for surety and costs have never really mattered. A good example, is the use of NET-EN despite adequate evidence of its dangers, and the free distribution of oral pills despite their exhorbitant prices. Oral pills were accepted by the planners of the National Family Planning Programme for use in pilot projects for the benefit of rural women and Net-En was approved for marketing in India. All this because the focus had all through been, not on discovering or inventing safe technologics but on pushing those which fulfilled certain targets. Similarly, if we were serious about providing contraceptive or abortion services to women, these should have been an integral part of the most basic health services. This however, is not the case. Despite all the glib talk about health for all by 2000 AD and about full coverage of populations with minimum health services (Primary Health Care), the majority, specially the poor, still have no access to health services (GOI, 1983). People are much more familiar with targets, force, paycuts and withholding of increments for not getting 'cases' rather than with choices in family planning methods. They don't seem to know that the countrv's health services were in fact meant to provide these choices to them and all that goes along with making such a choice.

Yet another related issue is that a large number of women cannot avail even such services as are available, even if they want to. This is primarily because of the pressures exerted by the family and their own insecurity within that structure. Despite voluminous reports on the status of women, national celebrations of the international womens' year and huge amounts of money going down the drain into the so-called women's upliftment schemes, the status of women remains at a level where the majority have little say in matters as intimate as their own selves.

The problem of women who need the test for medical reasons or for failure of contraception is not very different.

tion of their becoming a prey to the greedy private practitioner, or the ill informed doctor would not arise. There are any number of safe and equally cheap pregnancy tests that the health service ought to be providing to women who really need it (*EPW*, 1987).

It is not difficult to see then that the medical establishment is not interested in safety for the user but in surety of contraception. It is not concerned with making services accessible to people but wants to catch them as targets for surer methods like sterilisation. It is not bothered about the poverty or backwardness of the people but is geared to control them.

The second reason for using pregnancy tests was the need to be selective about the baby's sex. A couple detects pregnancy, goes for amniocentesis and then opts for abortion if it is a female foetus. In Maharashtra alone, between 1982 to 1986 the number of clinics performing amniocentesis has increased from 10 to about 600. The estimated numbers of abortions done for expelling female fetuses in 1985 has been 40,000 (GOI, 1986). This pattern, frighteningly prevalent in most parts of the country, is yet another reflection of a social malady. Instead of provoking its professional ethics and fighting the evil openly, the medical profession chooses to keep quiet or fights against restrictions over the use of amniocentesis, in the name of freedom of the medical practitioners to choose the best for their clients. The medical researcher on the other hand continues to add to the list of oppressive technologies, techniques such as those used for sex pre-selection which promotes the practice of discrimination against female foetuses. At the same time they also make the obstetrician the complete controller who now diagnoses as well as dispenses and thus acquires godly powers!

These questions lead us to the reality that the very need for pregnancy testing in the majority of the cases, largely arises out of maladies located in the social situation as well as the inefficiency and inadequacy of the health service system. Focussing on this need and not its causes, finding technologies for satisfying this need without touching its causes, can at best be called a symptomatic approach to tackling deeprooted problems. Such technologies in fact not only divert attention from the real nature of the problem but also provide cover for the system's wider failures. Accepting them and using them for controlling female fertility amounts to accepting an out-right neo-malthusian strategy for the problems of population.

EP Forte is not the only drug which falls under this group of reactionary technologies. When in 1984 women protested against amniocentesis the government had expressed much concern at the loss of female foetuses and the exploitation of women by "clandestine private practioners". In a seminar organised by the Additional Secretary and Commissioner of Family Welfare in December 1986 at Nirman Bhavan, the steps suggested to tackle the problem included (1) Legal reforms, specially in the Medical Termination of Pregnancy Act 1971, (2) Social awareness through educational programmes and upliftment of women (3) Restricted permission for doing amniocentesis to public institutions (4) More than one doctor's recommendation for such a test. The government's representatives were very sympathetic to these ideas but they argued that the legal system could not be changed. This was perhaps because the MTP Act provides for abortion in a cases where contraceptions has failed and there is no way in which this could be disproved. It is well known that MTP has become a technology in use for the family planning programme and it is no wonder that the government is not inclined towards making this explicit. At the same time it is impossible to introduce stringent measures within the legal system without making the conditions under which abortions take place more restricted and explicit. The government's reluctance to change the law is projected as the 'helplessness' of its legal system. It is ironical that a government which passed the Muslim Women's Bill despite all the opposition and social presures should plead helplessness and invoke 'social awareness' to put an end to the misuse of amniocentesis.

Yet another example is the wide range of technologies used in Family Planing Programme starting from IUD, tubectomy, oral contraceptives, abortions and laparoscopy. All of these were considered for family planning and within the programme, acceptance and desire for family planning were simply taken as issues of availability of technology. The programme for a long time refused to take into account the major socio-economic dimensions of family. This very narrow approach to the problems of population is obviously not an un-intended accident. The waxing and waning attraction towards compulsion at one time and incentives at another time is in itself an indication of the limited range of options within which given technologies are expected to be effective. It also reflects the direction and nature of the overall developmental policies.

The latest in the barrage of technology is the case of Indo-US Vaccination Action Programme (*EPW*, 1987, correspondence). In the health programmes for mothers and children as well as the general population, vaccines have been in use since independence. Despite the availability of these well known technologies, the diseases against which they are effective continue to kill and maim. The only exception is smallpox, a disease that continued for decades despite the use of vaccines in this country. Finally, when it was contained, it was not only because there was a vaccine, but because a better understanding of the epidemiology of smallpox developed over time and provided an alternative strategy.

Suddenly, however, the faith of a set of experts in vaccines has been revived and they have signed a collaborative scheme with the US. Will they now test better vaccines on the Indian population? Even if we believe the argument that only vaccines needed in India will be tested like the cholera vaccine (or rabies and pneumonia vaccines etc.), we have to answer a very basic set of question. Firstly, what is the use of giving effective cholera vaccine to a people who are to perish in drought, without food and drinking water? Even if cholera is to be fought, have we shown that it is possible with the use of vaccines alone, rather than together with the provision of drinking water, food rations and sanitation? Over and above all this, do we have an understanding of the dynamics of morbidity and mortality caused by these diseases and their load and extent to be able to predict costs, set priorities and do some kind of monitoring? With obvious contempt for even the rhetorics of 'scientific rationality' vaccine technology is being glorified. This is not because what it prevents is our priority health problem but because

there is a technology which creates the aura of action and concern for the suffering of people without really touching the cause of that suffering.

These examples illustrate that again and again the system clutches at technologies which promise relief from suffering without really changing some of the social constraints.

Therefore, in the case of EP Forte and its widespread usage, it would be wrong to blame the lack of continuing education on non-availability of information to doctors. These may be peripheral reasons, the main reason being the underlying ideological bias of the 'scientific rationality' which is taught, accepted and propagated within the medical establishment. It is because of this ideological regimentation (where all technology available must be accepted and used and ill health should be seen as a medical problem alone), that the medical profession at large has failed to stand up together and speak in the interest of its clients. A good number in the profession have in fact taken advantage of the trend to make their own profits in the shape of money, position and security. This has been possible because they have been backed by those interested in actively or passively propagating technologies like EP Forte. The drug companeis who use these doctors, also paralyse the legal system which invariably finds itself 'helpless and incapable' of banning killer drugs. The control machinery has become ineffective and is listening to the 'impressions and personal experiences' of the so called scientists (the senior medical practioners) rather than to the meticulously collected objective evidence presented by those who are demanding a ban on the use of EP Forte.

Where the inappropriate usage of EP Forte (and other medical technologies) can be traced to maladies at so many levels, then the issue is not of fighting against just one drug, one test or one technique. The issue is of weaving this protest into the wider political movement against a system that breeds, nurtures and protects oppressive technologies and ignores those technologies which could be better utilised in the interest of the people.

Polio, Politics, Publicity, and Duplicity

Ethical Aspects of Development of Salk Vaccine

allan m brandt

This paper is an historical account of the discovery, testing, and early distribution of the Salk polio vaccine. The discovery posed fundamental dilemmas of medical research, pharmaceutical production and public health. This paper assesses the ethical problems which arose, and examines critically their resolution.

The great public demand which the discovery of the vaccine generated created a need for federal control which was only partly met. The federal government did not have sufficient institutional and legal mechanisms to assure the safety of the vaccine and protect the public. This discussion illustrates the failure of the government to keep pace with medical technology.

Reprinted from International Journal of Health Services, *vol 8, no 2, 1978.*

THE introduction of a new biological pharmaceutical presents a host of medico ethical dilemmas. The debate surrounding the nationwide influenza vaccination programme suggests only a few of the multifarious difficulties involved. Each step in the process—from the initial funding for research to the testing, licensing, commercial production, and distribution of the drug—is wrought with serious judgmental considerations of both a medical and moral nature. If one accepts the public welfare as the preeminent value in the discovery and distribution of a new drug, the role of the government is of primary importance.

The history of the Salk polio vaccine is revealing in this regard. The discovery marks an important episode not only in the growth of immunology, but, most significantly, in the history of public health. The demands made upon the government and the government's response to these demands provide critical insights into the recent course of public health in America. This paper will examine the history of the Salk vaccine in light of the ethical judgments involved.[1]

The vaccine discovered by Salk in 1952 marked the culmination of the efforts of the National Foundation for Infantile Paralysis to secure an immunological agent against polio. The Foundation had grown out of efforts to raise funds for Franklin D. Roosevelt's Warm Springs retreat during the Depression. In consultation with public relations firms, Roosevelt's former law partner, Basil O'Connor, organised a series of "President's Birthday Balls" in 1934 with the slogan: "Dance so that others may walk" (3, p. 16). In 1937 Roosevelt announced the formation of the National Foundation for Infantile Paralysis (NFIP) for the purpose of ensuring "that every responsible research agency in this country is adequately financed to carry out investigations into the cause of infantile paralysis and the methods by which it may be prevented" (5). Basil O'Connor became the president of the new organisation. The creation of the Foundation signaled a major new direction in the history of American medical philanthropy. The appeal for funds now utilised sophisticated public relations techniques (6). Of significance was the dramatic extension of the traditional concept of philanthropy, as the National Foundation now sought funds from everyone, not just the affluent. Radio spots requested that dimes be sent directly to FDR in honor of his birthday on January 30, 1938. More than 2,600,000 dimes "marched" into the White House, inundating the mail room (3, p. 18). Thus was coined the title "March of Dimes."

The Foundation pioneered in the techniques of modern fund raising with its mass appeals, use of media, public relations, and a corps of volunteers. The unprecedented doorbell campaign—the "Mothers' March on Polio"—began in earnest; the Foundation put its cadres into the sheets. Their ability to raise funds, even during the most trying economic circumstances, must be rated remarkable. By the 1950s the National Foundation had developed the perfect form of philinthropy for the burgeoning consumer culture.[2] The concept of philanthropy as consummerism—with donors promised personal benefits—was to a great degree the contribution of the March of Dimes.

Why did poliomyelitis become the rallying point for millions of Americans? One logical answer is, of course, Franklin Roosevelt's personal battle with the disease. Despite FDR's attempts to conceal his infirmity, a new media age made polio the most prominent of diseases. But Roosevelt merely symbolised a more general perception that polio was a peculiarly American malady. More dangerous in affluent nations, polio became America's target although other diseases and medical afflictions were really more common.[3] An increasingly child-oriented society could not tolerate a disease which crippled its young.[4] In addition, the National Foundation had a remarkably powerful influence on the whole direction of American medical research and health care priorities, a topic that demands more attention than is possible here.

There can be little doubt that the Foundation put its funds into the right hands. Through the use of long-term, substantive grants awarded to eminent researchers and institutions, the NFIP insured the continuity of polio research. By 1948 a series of important epidemiological studies had been made under the Foundation's auspices. Most important was the discovery of Drs. John Enders, Thomas Weller, and Frederic Robbins, all of Harvard University, that poliovirus could be cultivated in nonnervous tissue (4, pp. 369-381; 9). This Nobel Prize-winning discovery virtually assured that a polio vaccine could be produced. A race, with bitter political and personal overtones, ensued.

Development of Salk Vaccine

Dr. Jonas Salk began his research on polio immunisation in 1951 under a grant from the National Foundation. Within a year he had successfully immunised monkeys in his laboratory at the University of Pittsburgh. Confident that he had found the key to immunisation in a killed virus vaccine, Salk proceeded to test his discovery on human subjects.

The first of these experiments was conducted on children from the D. T. Watson Home for Crippled Children. Risk was reduced by vaccinating these children, who had already had polio and were thus immune prior to injection. Salk inoculated 43 children with no adverse reactions. He later commented, "When you inoculate children with a polio vaccine, you don't sleep well for two or three months" (1, p. 139).

Salk continued his experiments at the Polk State School, where he again inoculated children with his test vaccine. Unlike the polio victims at the Watson Home, these children, who were mental defectives, had no history of polio and thus much lower antibody titer, significantly increasing the danger of the test. The ethical standards applied here, though in no way unusual in the 1950s, must be questioned. Dr. Tom Rivers, one of the most eminent virologists in the history of modern immunology, in reviewing an experiment similar to Salk's, voiced concern about the morality of such a test (10, pp. 466-467):

> I think that if someone wants to use adults as volunteers to try out a new drug or vaccine, that is perfectly all right, provided that the adult has been told about the nature of the disease he is exposing himself to, has been completely informed about the nature of the agent he is to receive, and has been told the chances for success or failure . . . An adult can do what he wants, but the same does not hold true for a mentally defective child. Many of these children did not have mommas or poppas, or if they did their mommas didn't give a damn about them.

Fortunately, Salk's confidence in the vaccine was borne out by the results of these initial human tests. But Dr. John R. Paul, in his definitive history of poliomyelitis, pointed out what failure may have entailed (4, p. 418):

> Had the experiments gone wrong at this point there might have been a tremendous outcry. Some would have called it unnecessarily hasty to use so many subjects all at once... And others would have called it a crime to subject helpless children and adults to this sort of experimentation.

It would seem from this analysis that an experiment on human subjects is ethical if successful, unethical if a failure—a dubious formulation. No government guidelines or requirements for human testing existed at that time.

Salk's success buoyed his faith in the vaccine. In presenting his findings to the medical community, he was, however, more cautious (11):

> Although the results obtained in these studies can be regarded as encouraging, they should not be interpreted to indicate that a practical vaccine is now at hand. . . .It will now be necessary to establish precisely the limits within which the effects here described can be reproduced with certainty.

The task of establishing the effectiveness and consistency of the new vaccine would not be Salk's alone.

Planning Field Trials

By the middle of 1953 the National Foundation had begun devising plans for a mass nationwide trial, the largest of its kind ever attempted. The Foundation established a Vaccine Advisory Committee (VAC) of eminent physicians and researchers headed by Tom Rivers to oversee the field trials. The NFIP's decision to conduct such a field trial meant that serious consideration of other forms of immunisation, particularly the attenuated vaccine, no longer was possible (4, pp. 423-425). The Foundation's position, though clearly understandable in light of the embryonic nature of attenuated vaccine research, sparked controversy and aroused bitterness. From this time onward, criticism of the [illegible] be an indeterminate mixture of scientific judgment and personal animosity.[5]

The National Foundation conducted affairs on a grand scale; the field trials slated for early 1945 were to be no exception. The NFIP with its newly created Vaccine Advisory Committee proceeded to design the trials in a direct, almost autocratic manner. After his initial discovery, Salk found his influence diminishing over subsequent decisions concerning testing, as did a host of other scientific advisers to the Foundation. Basil O'Connor, anxious to move forward with all possible speed within the bounds of safety, pushed the VAC in the singular direction of conducting a definitive test (10, pp. 495-500).

Scientific advisers dashed over the design of the trials. Originally, the Foundation planned to vaccinate volunteers and compare the rate of paralytic polio among this group to a control group of nonvaccinated children. This format had the advantage of being easy to administer [illegible] and evaluate, and in addition gave all volunteers the potential benefit of the vaccine. The Vaccine Advisory Committee insisted, however, that a "double-blind" test was necessary to eliminate the socioeconomic bias of the volunteer group and thus provide a scientifically unassailable evaluation. Under this test, half the volunteers would receive vaccine, half placebo.

This decision infuriated the increasingly confident Salk who called the double-blind test a "fetish of orthodoxy. . ." Salk clearly exposed the ethical dilemma of using a placebo in an impassioned letter to O'Connor (1, pp. 191-192):

> . . .if we are aware of the fact that the presence of antibody is effective in preventing the experimental disease in animals and in man, then what moral justification can there be for the purpose of determining whether or not a procedure that produces antibody formation is effective. . .[?] I would feel that every child who is injected with a placebo and becomes paralysed will do so at my hands.

Such an experiment, argued Salk, "would make Hippocrates turn over in his grave."

It is not difficult to sympathise with Salk's viewpoint. With a double-blind test the effectiveness of his vaccine would essentially be proven by the contraction of polio among those children who received placebo. But the emotional content of Salk's plea would also seem to indicate the importance of removing the test from the hands of the discoverer. In a sense, Salk favored an early limited distribution of his vaccine as a test for efficiency, not a carefully controlled, scientifically conducted examination. Sure of the safety and effectiveness of his vaccine, he actually jeopardised its full acceptance in the medical community. This is not to question Salk's scientific ethics or his personal morality, but rather to suggest the difficulties of participating in the evaluation of one's own researches.

Though the National Foundation took full responsibility for the field trials, the VAC commissioned Dr. Thomas Francis of the University of Michigan to evaluate the trials. Francis, a pioneer in the fields of microbiology and immunology, commanded unquestioned respect in the scientific community. The Foundation assured the University of Michigan ample funds to assist in Francis' evaluation. He demanded complete control of the evaluation—with no outside pressure, timetable, or supervision—and O'Connor agreed to these stipulations. Francis also insisted on an injected control

group in at least some states. The decision to have Francis assess the vaccine insured an irreproachable trial.

Before a trial could be attempted, however, the difficult transition from an experimental, laboratory-produced vaccine to a consistent, commercially manufactured vaccine had to be negotiated. Until commercial laboratories could produce vaccine, all talk of a field trial was really premature. Although the National Foundation contacted five major pharmaceutical companies to produce vaccine for the field trials, a complete draft of the requirement for production did not evolve until early 1954, only several months before the trials began (1, pp. 207-211). The Vaccine Advisory Committee supervised the shift to commercial production, making two critically important recommendations. First, the Committee required that Salk conduct an initial trial on at least 5,000 children using commercially produced vaccine before undertaking nationwide trials. And secondly, *all* commercial vaccine for the field trials had to undergo safety tests in three laboratories—the producers', Salk's and the U. S. Public Health Service's Division of Biological Control (12).

The decision to test commercial vaccine in the federally operated lab represents the difficulty of the government's position. The government had no legal role in the trial; no licence was required for such an experiment. The Food and Drug Administration only required that the test drug be safe, not necessarily effective(13). A major medical advance was in the making, with the government's only capacity an essentially extralegal one. Moreover, when it came time for the licensing of the vaccine, the Public Health Service would be in the dark. "We wouldn't know enough about the vaccine and the ins and outs of its manufacture", remarked a Public Health Service official. "We would not be able to act on licence applications for months. But the public would want action in hours" (1, p. 209).

With no official role in the testing of the vaccine but badly needing most information, the Public Health Service gladly accepted the functions allocated by the Vaccine Advisory Committee of the National Foundation. Indeed, the Division of Biological Control, under the direction of Dr. William Workman, scrutinised procedures to the point of threatening the trials. Workman and other government officials realised that, although they had no legal sanctions, they had the responsibility of insuring a safe, effective vaccine (1, p. 208). Moreover, the National Foundation recognised the importance of having the blessing of the Public Health Service before conducting its trials.

Opposition to Trials

Scientific opposition to Salk's vaccine remained formidable as the trials approached. Some scientists had difficulty duplicating Salk's inactivation process in their own labs, while others questioned the viability of a killed virus vaccine. Dr. Albert Milzer had been unable to reproduce the Salk vaccine in his laboratory at the University of Chicago. He repeatedly found live virus in the vaccine—an ominous result. Dr. Albert Sabin, at work on an oral, attenuated vaccine, became Salk's chief antagonist. Only one month before the field trial was set to begin, Sabin called the test "premature". Salk and the National Foundation attempted to combat the criticism: "I give every possible assurance I can and that medical science can that the antipolio vaccine will be safe. I will personally be responsible for the vaccine", declared Salk (14, 15).

More troublesome than this criticism, however, were the continued difficulties of the commercial producers in their attempts to replicate Salk's vaccine *en masse*. Scientists at the Public Health Service's Division of Biological Control harbored serious doubts about the abilities of the manufacturers to produce consistently safe vaccine. This reflected, in part, inexperience in the histopathology of polio (10, p. 513). But it also revealed a very real production problem. In March 1954, Dr. William Workman suggested that the field trials be postponed:

> I again come to the conclusion that the specifications and minimum requirements. . .are inadequate to assure the reasonable regularity of production of a vaccine of acceptable safety to be used in the field study. Under the circumstances, I cannot escape the feeling that an occasional lot. . .which does pass the test, may actually contain living virus and be unsafe for use. My recommendation is that the proposed field studies be postponed until—(1) specifications and minimum requirements can be revised to give greater assurance of the safety of the final product; (2) it has been shown that the vaccine prepared in accordance with such specifications meets acceptable criteria for safety (1, p. 221).

It should be emphasised, however, that the government had no legal means of postponing the trials. The National Institutes of Health and the National Foundation agreed that, rather than revising the safety tests themselves, companies must produce eleven *consecutive* lots of safe vaccine for any to be acceptable for use. With this agreement, plans proceeded for the field trials.

Despite the persistent opposition within the scientific community, the National Foundation and the press stimulated public optimism for the vaccine's success. The dual role of the National Foundation—philanthropic and scientific—created tensions. The profusion of positive press release, essential to fill the Foundation's coffers, jeopardised scientific judgments (3, pp. 82-85). The National Foundation announced publicly the plans for a mass field trial months before a commercial laboratory had produced any vaccine (16).

The press played upon the drama of the situation; no medical discovery before or since has been covered as intensely. Beginning in 1953, progress in the vaccine's development was regularly front-page news in the *New York Times*. Press reports were often filled with speculation (17):

> If the vaccine fulfills the hope that at last a way has been found to cope with poliomyelitis as effectively as public health officers cope with smallpox or typhus, Dr. Salk will have scored one of the greatest triumphs in the history of medicine.

Although Salk and the National Foundation attempted to discourage such optimistic conjecture, Basil O'Connor's euphoria could not be contained. He declared that the development of the vaccine had brought the fight against polio to the "verge of victory" (18). The *New York Times Magazine* called the trials the "climax of a stirring medical drama" (19).

The vaccine's notoriety undermined the control of the scientific community. The public now clamored for the vaccine, making it increasingly difficult for scientists with reservations to resist the demand for mass testing. Sabin's attacks on the vaccine, became more personal in nature: "Let us not confuse justifiable optimism with achievement" (20). And Salk's defence became less scientific: "I have the courage of

my convictions. I couldn't do it unless I was more critical of myself than others are of me. It is courage based on confidence, not daring, and it's confidence based on experience" (21). Salk continued to announce that he would take "personal responsibility" for the safety of the inoculation—a courageous, if ill-advised stand (22). The *New York Times* felt qualified to endorse the trials, remarking (23):

> No matter how important a medical discovery may be, there are always skeptics who try to strip it of importance. We need these skeptics, but sometimes they may be nuisances.

At this point the skeptics were threatening the test. Several states withdrew, from cooperation in the trials after Walter Winchell announced on national television and radio that the vaccine "may be a killer" (24).

This is not to argue that the press and public should have no role in a medical discovery, but rather that, in this kind of atmosphere, where public demands and expectations are great, sound scientific judgment may be jeopardised. *The Salk vaccine was sold to the public before its safety and efficacy were proven.*

The National Foundation must bear some of the responsibility for the public fervor which surrounded the field trials. Perhaps the most objectionable of all the Foundation's pronouncements was that the test was exclusively designed to test the efficiency of the vaccine. According to the Foundation, safety had already been conclusively demonstrated. In light of the production difficulties, this was a particularly bold assertion. The NFIP struck the word "experiment" from its literature; this was a "trial" vaccine, not an "experimental" vaccine. Although the test was conducted on a voluntary basis, the *quality* of informed consent is thus highly questionable.[6]

On April 25, 1954 the Vaccine Advisory Committee set up final guidelines, giving its approval for the trials. The United States Public Health Service issued the following statement (26):

> We believe that the judgment of the Vaccine Advisory Committee is sound and that the National Foundation for Infantile Paralysis is justified in proceeding according to the Committee's recommendation.

The next day the field trials began. With more than 1,800,000 children participating, the trials mark the largest clinical test using human subjects in the history of medical science. No medical experiment ever held such public attention. According to a Gallup Poll conducted in May 1954, 90 per cent of the American people knew of the field trials, more than could identify the full name of the President of the United States (1, p. 268).

The test, conducted in 45 states, used placebo controls in 84 areas and observed, nonvaccinated controls in 127 areas. More than 400,000 children received three injections; about 200,000 of these actually received salt-water placebo injections rather than the test vaccine. Along with blood samples to test antibody titer, Dr. Thomas Francis now had the information needed for a conclusive evaluation of the vaccine (1, pp. 238-261).

Speculation was rampant concerning the results of the field trials, but Francis promised no annuoncements until the spring of 1955. He had more than 144 million pieces of information to assemble and review. Some days the Evaluation Center's morning mail filled an entire elevator (1, p. 255).

A critical problem faced the National Foundation during this interim period while awaiting Francis' report. Without a federal licence (which could not be obtained until the vaccine was finally evaluated) and without advance orders, the pharmaceutical companies could not afford to continue to produce vaccine. It was not difficult to foresee a situation in which the vaccine would be found to be safe and effective, and yet there would be no vaccine available for the 1956 polio season. Basil O'Connor, with typical boldness, ordered $ 9 million worth of vaccine from six pharmaceutical companies--an expensive gamble on the vaccine's approval. Of course, if the Congress had been willing to allocate funds, this risk could have been avoided. But the government seemed content to let the National Foundation carry the ball.

On April 12, 1955, the tenth anniversay of Franklin Roosevelt's death, Francis released his evaluation, one of the most comprehensive epidemiological studies ever conducted. According to Francis, the safety of the vaccine was "powerfully affirmed" (27, 28). This is an interesting observation in view of the National Foundation's reluctance to consider the trials a test of safety. Francis found the vaccine 80 to 90 per cent effective in placebo-controlled areas, slightly less in observed controlled districts (28, pp. 15-19). In short, the vaccine appeared to be a tremendous success. The nation celebrated; for many parents, it seemed, the anxious summers were over.

The successful development of the polio shot characterised the Eisenhower years as the moon shot did a later era. The image of the scientist-hero, unhampered by government intervention, held great appeal. The press proclaimed Salk a national demigod, while some colleagues, resentful of all the attention he received, suspected him a demagogue. The vaccine became a perfect cause for an age in which ideology was suspect.[7] The scientific atmosphere of the 1950s was wrought with Cold War overtones. The vaccine, an affirmation of American scientific and technological progress, was viewed as a triumph of the American system. American science, pragmatic and purposeful, demonstrated the continued viability of the promise of American life.

In Washington, Ms Olveta Culp Hobby, Eisenhower's Secretary of Department of Health, Education, and Welfare, signed licences for six companies to produce vaccine. These companies had, of course, been producing vaccine all along; the licences gave them authority to distribute it.[8] The National Foundation's vaccination programme for school children began immediately, with youngsters who had received placebo during the field trials given top priority. For all intents and purposes this should have been the dramatic conclusion to the conquest of polio. Unfortunately, it was not.

The Cutter Crisis

On April 26, 1955, two weeks after Francis' Ann Arbor proclamation of safety, five cases of paralytic polio were reported among children who had just received vaccine. All five victims, it was found, had received vaccine from the Cutter Laboratories in California. Surgeon General Leonard Scheele requested that Cutter recall all its vaccine pending an investigation. Remarkably, the government had no power to order the Cutter Labs to withdraw the vaccine, but Cutter readily complied. The infamous "Cutter Incident" would, however, eventually encompass 25 states and Hawaii, 260 cases of polio, and 11 deaths (1, p. 316).

These cases of polio cast an ominous cloud over the Salk vaccine, the National Foundation, the pharmaceutical companies, and the National Institutes of Health. What had gone wrong with the most rigorously tested drug in medical history? The most obvious cause of the problems was that the careful triplicate testing of the field trials had not been continued for the licensed vaccine (12, pp. 329-331). Written protocols submitted by the manufacturers to the Division of Biological Control were the only legal requirement. The Division had the right to make spot checks, but did not exercise this option. Moreover, the consistency standards of repeated safe batches which had been devised for the field trials were not required of licensed vaccine. In brief, safety precautions for commercially produced, licensed vaccine fell far short of the guidelines used for the field trials.

During a series of meetings of top virologists and advisers called together by Surgeon General Scheele, it was decided to let the vaccination programme continue. But this consensus began to erode quickly. Dr. John Enders, regretting his approval for continuing the programme, wrote to Dr. William Sebrell, the Director of the National Institutes of Health (32):

> I am forced to conclude that active virus might be present in certain finished lots of vaccine prepared by any or all of the manufacturers concerned. I cannot, therefore, longer assert my confidence that the poliomyelitis vaccine now being distributed and injected consists solely of inactivated vaccine and in consequence, of harmless virus.

On May 7, Scheele *requested* that the national vaccination programme be suspended pending further studies.

Scientific criticism of the Salk vaccine intensified. In June, Enders and Sabin testified before a House subcommittee investigating the crisis that the vaccination programme should be stopped and the licences withdrawn until safety could be conclusively proven. But they were overruled by an equally eminent group of scientists who expressed confidence in the quality of the vaccine if properly produced (33).

On June 9, Scheele released a Public Health Service "Technical Report" on the Salk vaccine, an attempt to explain and correct the problems which produced the Cutter crisis. The "white paper", though not a complete whitewash, was carefully written to avoid directing blame (34).

> The Salk vaccine applies new principles in the production of vital vaccines. The speed of its development, which reflected the increased tempo of all medical research, created problems in biologics control amenable to solution only with the accumulation of knowledge and experience. It is likely that problems of equal complexity will be raised by the development of other new vital vaccines.

This analysis obscured the inadequate preparations made by the Public Health Service for testing the vaccine. Despite the easily predictable demand for the vaccine, the Bureau of Biologics staff remained at only 35, insufficient to carefully scrutinise the commercial production process. Moreover, the protocols required of manufacturers did not provide enough information for proper safety-evaluation. The contrast between the careful tripartite testing of the trial vaccine and the testing of the commercial product is a remarkable example of the lackadaisical attitude of the government toward biological control.

The irresponsibility of the Cutter Laboratories must not be overlooked in evaluating the crisis. Repeated difficulties in producing safe vaccine were experienced by the Cutter Labs; 9 out of 27 lots produced had contained live virus and were discarded. Yet Cutter failed to report this inconsistency to the Bureau of Biologics; the company only submitted protocols for batches which passed their safety test (34). Cutter officials never asked for assistance from NIH or Salk. *Their ethical commitment to produce safe vaccine must thus be seriously questioned. But it must also be remembered that they acted entirely within the letter of the law.* The NIH had no consistency requirement and did not require reports on discarded vaccine or production difficulties.

The Public Health Service's "white paper" explained the manufacturing problems in terms of inadequate sensitivity of the safety tests (34, p. 17):

> Each producer had had difficulties in processing and testing materials at various stages of production. Because some lots were obviously unsatisfactory they were not submitted for release, and therefore no protocols on them were submitted by the manufacturers. These experiences showed the need for more sensitive and better controlled testing methods, and for greater attention to the history of consecutive lots.

The Public Health Service revised the minimum requirements for production in light of the Cutter incident, making them mandatory standards. The Division of Biological Control was reorganised, becoming the Division of Biologics Standards with larger facilities and a fourfold increase in staff.

The relationship between the commercial producers and the federal government lay at the heart of the Cutter incident. This association became the target of serious investigations in the days following the tragedy. Victor Haas, the Director of the National Microbiological Institute, a division of NIH, evaluated the government-pharmaceutical connection in a series of memos to Sebrell in May 1955.[9] Haas argued that the responsibility for safety must ultimately rest with the manufacturers, and that the government could not (and should not) participate intensively in the safety testing of biologic products (35):

> It has been the principle of operation that this intensive participation in what is essentially a part of the manufacturing process, properly should be only a temporary activity for the Laboratory of Biologics Control. Once it has been established that manufacturers can produce safe material (and production experience and field trials of last summer formed the basis for licensing manufacturers for polio vaccine), this principle of operation would assume that periodic plant inspection, knowledge of the capabilities of supervisory personnel, review of protocols, and spot-testing of materials would suffice to assure us of continuing acceptability of any product within the limits imposed by available knowledge and human acceptability to error.

Intensive and continuous testing in government laboratories, Haas believed, would destroy industrial initiative and responsibility. According to his evaluation, more testing and inspection would not have prevented the Cutter incident. This is a dubious assertion, for certainly the manufacturing difficulties experienced by Cutter and the other pharmaceutical companies would have been revealed, raising questions of safety.

Finally, Haas suggested that it would be improper to overreact to the Cutter incident by revising existing standards of control. He ascribed the current fervor to the tremendous publicity which the polio vaccine had generated (35):

> Had the poliomyelitis vaccine been used on the same quantitative scale that applies to other biologicals and had an incident occurred, there would have been very little attention given it other than by the constituted authorities. The many factors which have gone into creating a demand for a safe and effective poliomyelitis vaccine, which would be available at the earliest possible time, should not force us to abandon careful and sound judgment as to what is the best method for the operation of biological control over the years.

The Cutter incident exposed the inherent weakness in the

argument for governmental laissez-faire with regard to biologics control and pharmaceutical production. The limited role of the federal government clearly reflected the Eisenhower political philosophy. Olveta Culp Hobby eventually lost her job, largely because of the vociferous criticism of her handling of the vaccine programme. In addition, the government's action was circumscribed by the miniscule legal powers of the Public Health Service, essentially unrevised since 1902, a time of relatively primitive pharmaceutical production. The government continued to assume that industrial interest in producing a safe product would ensure the public's safety.

In view of the federal government's minor role, the National Foundation assumed massive responsibilities in the development and distribution of the vaccine. Combining the functions of fund-raising, research, testing, and distribution, the National Foundation often found its multiple roles conflicting. Although well-intentioned, the publicity mill created an atmosphere in which demand threatened to outstrip sound scientific decision making. In such an environment, ethical questions can become obscured. The field trial, for example, though brilliantly engineered and promoted, and meticulously evaluated, lacked truly informed consent.

The ethical aspects involved in the development and distribution of the Salk vaccine are varied and complex, and the historian must be leery of second-guessed, overarched generalisations. But three key issues which demand continued attention emerge. First, testing with human subjects presents a series of problematic considerations, from the suspect use of mentally defective children to the use of healthy, parent-volunteerd youngsters. High ethical standards for defining risk-benefit ratios must be exercised in such investigations; use of placebos complicates such assessment. Moreover, informed consent is liable to compromise (36). Second, the obligation of pharmaceutical companies to manufacture safe products cannot be assumed, especially when pressures to market a new drug become intense. The third point is most striking: the federal government's minimal role in a major scientific advance. Although the government cannot be the final arbiter of ethical medical judgment, it is the only body which can provide a central direction and standard for these practices. By abdicating a more active role, the government invited the possibility for crisis. The Salk episode seems to indicate a less than complete commitment by the government to the public welfare.

In the years since the discovery of the Salk vaccine, the problems of pharmaceutical control have expanded rather than diminished. The capacity of the government has remained limited in overseeing industry. The Government Accounting Office, Congress' investigative arm, recently attacked the lax attitude of the Food and Drug Administration's drug testing (37, 38). According to the GAO's report, human subjects are exposed to unnecessary risks and the FDA has approved new drugs for public use on the basis of highly questionable data. FDA attempts at self-investigation have proven largely useless (39). The FDA has failed to enforce its standards and, according to many reports, has served as a lackey to the major pharmaceutical companies (40). In its mission of public protection, the FDA, by any standards, has proven to be grossly inefficient.

The history of the Salk vaccine, from the initial research through testing and production, speaks clearly to the present. The institutional connections through which a new drug is channelled from laboratory to market remain uncertain, subject to frequent short-circuit. The time between discovery and production has steadily decreased, augmenting the difficulties implicit in regulation. Most importantly, the federal government has failed to keep pace with the rapid innovations in medical and pharmaceutical practice, at great cost to the public welfare.

Notes

1. Several studies of the development of the Salk vaccine have been written, although none is definitive. The most comprehensive of these is *Breakthrough: The Saga of Jonas Salk* by Richard Carter (1). Rich in detail, though weak in analysis, this book was particularly helpful in my study. Also recommended are John R. Wilson's *Margin of Safety* (2) and Aaron K. Klein's *Trial By Fury: The Polio Vaccine Controversy* (3). The definitive medical history of poliomyelitis is *A History of Poliomyelitis* by John R. Paul (4).

   The archives of the National Foundation have unfortunately been closed to researchers. This rich collection of materials contains valuable information pertaining to the development and distribution of the Salk vaccine.
2. For a more extended analysis of the implications of consumer culture, see reference 7.
3. Nations with high standards of sanitation and personal hygiene actually prove to be more susceptible to enteric viral infections such as poliomyelitis (4, pp. 364-365).
4. For an explanation of attitudes toward children in the postwar era, see reference 8.
5. See references 1 and 2 for extended discussions of the bitter relationship between Salk and Dr. Albert Sabin of the University of Cincinnati.
6. Parental consent was required for a child to participate in the trial. Excellent essays on informed consent and human testing are contained in reference 25.
7. Excellent discussions of political and cultural life in the 1950s are contained in references 2 and 30.
8. One of the six companies was the Cutter Laboratories of Berkeley, California. The Region Oral History Office of the University of California at Berkeley recently completed an oral history memoir with individuals from this organisation, documenting its involvement with the vaccine (31).
9. These memoranda, marked "confidential" have only recently been opened to researchers as a result of a Freedom of Information suit. They are a highly valuable source for deciphering the government's view of its role in the development of the vaccine (35).

Pharmaceutical Industry in Latin America

BOTH the transnationalisation and oligopolisation of the pharmaceutical industry is well known. A few companies occupy a large percentage of the worldwide market. In 1985, the fifteen largest companies in the world were responsible for 37 per cent of the total pharmaceutial sales (US $ 79.8 billion).

This same phenomenon can be witnessed in Latin America, which accounts for 7 per cent of the world pharmaceutical market, or approximately US $ 5.5 billion. In 1985, the 10 leading companies in Latin America—all transnationals—captured 30.5 per cent of the pharmaceutical market in the seven countries studied (Argentina, Brazil, Columbia, Chile, Mexico, Peru and Venezuela). Sales in these countries reached US $ 4.13 billion that year.

The largest markets for pharmaceuticals in Latin America are Brazil, Mexico and Argentina, which are also the countries with the largest populations. In 1985, the total market in Latin America was valued at US $ 5.5 billion; 69.3 per cent of these products were sold in these three countries.

The most frequently sold products in the region are antibiotics, cough preparations, antirheumatics, analgesics and vitamins. This illustrates well the pattern of pharmaceutical consumption in this part of the world. On the one hand, while it is true that there is a high incidence of infectious illnesses justifying the use of antibiotics, these products are often used indiscriminately. Of more concern, however, is the fact that "cough and cold preparations", many of which are simply useless for the purpose intended, occupy second place on the list of sales. Analgesics and antirheumatics—symptomatic drugs—also occupy a preferential place, while products containing vitamins represent a considerable proportion of the sales, thanks to promotional campaigns which try to present them as a solution to the nutritional problems of the Latin American population.

The most startling fact, however, may be that "Novalgina", produced by HOECHST, occupies first place in the sales list, in spite of the fact that its principal active ingredient—Dipirona or Metamizole—has been withdrawn from the markets of many countries because it can produce agranulocytosis, a sometimes fatal blood condition.

Beyond Medical Solutions

guy poitevin

TAKING SIDES. The Choices Before the Health Worker by C. Sathyamala, Nirmala Sundharam and Nalini Bhanot. ANITRA, 1986, pp 320, copies available at B-7, 88/1 Safdarjung Enclave, New Delhi 110 029. Rs 70

THE authors address this sort of committed rural health handbook written in English to middle level health workers' engaged all over the country in rural health services. They take as a starting point, on the one hand, the arguments raised in the last 10 to 15 years against the effectiveness of modern medicine, and the other hand, the failure of the alternative tried out to substantially improve the health situation in rural India. The reason for both is assumed to be the exploitative nature of a society of which the social, political and economic forces by shaping the way of life of the people produce the disases affecting by and large the population.

Those who immediately and hopelessly confront this social and economic reality of the people they work with, are the middle level health workers upon whom the health services actually rest. Yet, "it is these workers who are least involved in a critical examination of their work". Firstly, being located in the lower rungs of the hierarchy of medical services, they are just expected to follow orders. Secondly, their training does not prepare them to conceive, let alone to suggest, appropriate alternatives. Frustration, insensitiveness or despair eventually overcome them. Even so, out of their experience of training programmes, the authors are convinced that those scattered and isolated health workers could and should achieve a lot once helped to develop the proper perspective required with regard to rural health care. The four sections of the book make, therefore, an attempt to help middle level health agents to learn from their disillusion, and instead of relapsing into the apathy or the self-complacently irresponsible stands of public health employees, lead them towards attitudes and practices of social health activism.

The first section describes the baffling experience of Radha, a woman health worker who happens to leave her city hospital to work in a rural dispensary. Absolutely unprepared for this by her training and previous experience, she is progressively confronted with a series of puzzling questions regarding unexpected attitudes and behaviour of the villagers. She painfully realises that her medical knowledge and skill prove of little use. Unable to cope with too many doubts, she feels out of place, she is frustrated: she comes back to her city hopsital.

Around eight common incidents which helplessly bewilder her in the course of ther work, are structured eight chapters which discuss the issues involved. They clarify the health riddles that Radha could not solve on account of her inability to understand the nature of the constraints which inexorably bear upon people's lives. She had only medical answers of a curative type to issues and needs which required first of all a social and psychological analytical insight. The inadequacies of her technological responses lead her to experience that as a pure medical agent she is unfit to meet the health problems of a common man. The following are the questions which pushed her to the limit and that the book, in a second part of the section, helps the health worker to firstly come to terms with while embarking in tasks of rural health care:

> Why don't people rush to get treated early?
> Why do people have faith in local healers?
> Why don't common people have satisfactory access to health services?
> Why are rural areas wanting in good medical practitioners?
> Why do people not implement even simple health messages?
> Why should a health worker know whether and to what extent people are poor or rich, influential or looked down upon? Aren't diseases independent of any other consideration?
> Why do people prefer to impoverish themselves with too many children?
> Why is it that a few people avail of so many health facilities and so many have so little of them?

The first section shows how the health care system as a development asset, no more no less than land, water, credit system, etc., obtains the status of a commodity socially appropriated by those who can afford it or snatch it in proportion to their social, economic and political position of power. As a consequence, ill-health is an unequal access to health commodities when these latter are made unavailable to some—actually many—by others—a few. Ill-health, therefore, mirrors and measures the state of deprivation of the subaltern. Ill-health is injustice and no simple natural disorder, no less than deforestation, unemployment, hunger and malnutrition, starvation wages, etc. The survival strategies of the deprived sections do not bear witness to their ignorance and backwardness but to the sway of iniquitous social forces. Once socially unaware and naively well-intentioned health workers like Radha understand this, they may hopefully realise that they had better feel anything but frustrated, if they really mean to avail the common man of their professional capabilities. But then, a second stumbling block threatens them.

Limitations of Established Modern Medicine

The second section deals with the inadequacies of the health workers which should not necessarily be ascribed to personal failure or inability. They are largely due to the inherent limitations of established modern medicine itself, the assumptions of which need questioning. Its development is as much based on scientific and rational principles as shaped by powerful economic and political groups. The second section expounds how the interests of doctors and big businessmen while contributing to the development of modern medicine, created also a limited view of health, diseases and healing process. New theories shifted the focus of disease causation from the social conditions that bred disease to the

immediate cause which was the germ, and the attention was diverted from poor nutrition, bad living and working conditions, exploitative labour and sex relations, etc. Disease became a physical event within an individual's body and care focussed on drugs, surgery and hospitals. Preventive measures dealt with immediate environment and diseases at the individual level. Health became a neutral and purely technical subject with its experts wielding absolute authority and monopoly on medical research management and health care policies. Big industrialists prompted modern medicine in order to increase the productivity of their workers through control of diseases by therapeutic techniques dealing with the immediate cause rather than the primary reason of illhealth, i e, the exploitative social relations of production. Modern medicine served the interests of those in power and developed to the extent it served these interests. Medical theories justified even the inferior roles of women.

As a matter of fact, the potent remedies and techniques developed with the support of businessmen had a very small part in reducing morbidity and mortality in the western countries. Their major decline had already taken place before specific medical technology was introduced. Death rates for measles, scarlet fever, tuberculosis and typhoid were already negligible by the time effective medical interventions were discovered. This tremendous achievement was not the effect of drugs nor doctors. It was due to improvement in living standards and public health measures. Biomedical technology once introduced had a very limited impact in improving the health status of the population and was responsible for no sharp decrease (except for polio) in mortality rates due to infectious diseases. Only 3.5 per cent of this decline took place because of medical interventions.

Ill-health in Independent India

The third section looks at the development of health services based on modern medicine in independent India with regard to the activities commonly undertaken by health workers in rural areas. Their limitations are pointed out and explained by the fact that they have not been planned keeping in mind the social and economic constraints of the majority of the villagers. As a result, health workers fail to meet the people's needs and by-pass the major causes of ill-health. Examining the policies of the government regarding these rural health programmes it is shown how health needs are actually used as a cover for serving the interests of the wealther sections of the rural population. A comprehensive review of the following rural health problems provides the essential results of the studies in the matter together with an analysis of the inter-related factors: a health-worker can afford to ignore neither of them. In each case the inadequacies of the government health policies are exposed and shown as basically due to the narrow health concepts of a purely curative medicine system absolutely blind, to the structural-social dimensions of health issues.

Health of children: Data on high mortality and diseases occurrences are related to structural constraints such as low nutritional status, low education status of women, inadequate access to medical care at birth and clean water, switch-over to tinned food, sex discriminations etc.

Health of women: Sex-ratio, life expectancy, mortality patterns and causes of death, maternal mortality, nutritional status, access to medical services, amniocentesis, infanticide are determined by the discriminatory effect of the social and/or economic degraded status of women on the one hand and on the other hand, by the medical profession being concerned not with women's health but with their (male) child's issue.

Health of adults: Given the over-all importance of their undernutrition, the reasons for this and the inadequacies of the nutritional programmes are exposed at length. No health worker may fail to be conversant with the misleading debates and approaches in the matter, with the deceitful talks on the so-called minimum wage, with the criminal exports of high protein food, with the decrease of acreage under cheaper coarse grains, with the export of rice, with the wasted buffer-stocks of cereals, etc. In such circumstances, "feeding programmes and minimum wages themselves become oppressive strategies in the long run".

Health education: Some examples show how the official health education as much as health advertising, resembles a harmful brainwashing by its explicitly or implicitly false or socio-culturally repressive messages, and by its concealment of important aspects. The demystification through a critical reading of all health messages may indeed prove a skill difficult to acquire when everybody takes for granted that education is merely a useful transfer of necessarily objective information. Actually, the assumptions of health education as commonly practiced should be denounced as often biased in such a way as to prove in the long run to actually impair the health status of the majority of people. The emphasis on individual responsibility and fault, the theory that health problems cannot be solved without a lot of money, the persuasion that the poor being ignorant, illiterate, superstitious and backward cannot but turn a deaf ear to health advice, the greater importance of men's health, the dependence on modern medicines and the knowledge of doctor's who alone know best, etc are message which conveniently remove the responsibility for ill-health from those who create and maintain "the exploitative practices" conducive to the poor's helplessness.

Family Planning Policy, (FPP): The theoretical and use-effectiveness of the commonly used contraceptive methods are examined and advice in given to make them helpful in improving women's health, as they are a meaningful way to this effect. The present failures are shown to be due to the implementing strategies and false assumptions such as the primary interest for population control at all costs, the belief that population growth is the cause of poverty and underdevelopment, etc. Family planning methods will succeed only if they are accompanied by an overall improvement in the socio-economic conditions of everybody. Failing this, the failure of the FPP can be considered an effective 'resistance' by the poor against the detrimental effects in their everyday life of government agricultural, social and economic policies: a survival strategy in front of socio-political mechanisms of deprivation.

The Village Health Worker's Scheme (1977): It is discussed and evaluated in relation to one basic principle, viz, the selection of the workers by the village community.

Curative services: Overuse and misuse of drugs, harmful role of drug companies, cost of drugs, etc. such problems are discussed and suggestions are made to help health workers overcome them.

Setting Off Again on the Right Foot

The fourth section takes stock of the principles for an adequate practice on the part of health workers: focus on changing the social environment for long term improvement in the health status of the most affected groups among local communities; understanding of and dealing with, the root causes of ill-health; choice of identifying oneself with those who are the most likely to fall sick; decision to operate with all of them as a collective; will to develop their insight into the reasons of their ill-health and foster their collective strength to act against them; attempt to make use of all resources available at the village and block level in a self-help spirit and with the firm conviction of one's own right to health vis-a-vis the government health services, etc. Then, an alternative model of health practices and health education is chalked out for the guidance of a middle level health worker already working in a rural hospital, dispensary or health centre but willing to spare time and resources to operate along the above guidelines although deprived of any experience of village work. Criteria are suggested regarding the selection of two or three villages to work in/around her centre; directives are given to help her develop a proper understanding of those villages through a close relation with people and renewed patterns of communication; the necessity is stressed of bringing people together for them to consider collectively their own needs, find out the reasons of their ill-health and seek solutions; the modalities of selection and training of a voluntary village health worker are clarified; explaining how to keep a diary, conduct a survey or a group discussion on health, from a permanent group of concerned people, deal with problems in a manner really conductive to the group's collective initiative and ability to act on its own, organise people to get due services from the government.

We thought proper to give this rather extensive account of the contents of the book under review to convince the health workers it is addressing of the many practical advantages they cannot fail to draw from it: well-researched statistical information compiling the most relevant data on each topic, didactic synthesis summing up studies otherwise scattered and lengthy, eight pages of referential documentation, a glossary. Considering the alarming and relentlessly resilient extent of ill-health of this country, one cannot but expect many health workers to make choices and definitely take sides along lines expounded in this reference and guide book. Every medical practitioner should hopefully have the opportunity of getting through this book and honestly questioning his practices and the methods of his/her institution in the light of the critical insights provided by this challenging appraisal of rural health problems.

The approach rightly avoids two pitfalls. The first one is to simply ask for multiplying the rural health services (doctors, drugs, dispensaries, injections, surgical equipment, etc) as others agitate for more dams only to bring more health and irrigation facilities to those who can lay hands upon them, with the same result in both cases: the majority of the needy is kept deprived of the means to meet its primary needs of health care and of the water required for irrigating its staple food crops. An unflinching sociological insight only may preserve us from short-sightedly lapsing into this trap. The most commendable quality of this review of rural health problems is its permanent claim to refer health issues to related structural-social factors and the overall marginalising dynamics engineered by them. Disparities in health status measure the extent of social discrimination and unequal appropriation of the means of health. There is no health nor ill-health *as such*: this approach has been the treachery of the purely curative or biomedical modern medicine for reasons known to its promoters. Both of them are outcomes and symptoms of a given social structuring on the one hand, and socio-cultural/anthropological systems of representations on the other hand.

The two critical questions to be raised concern, firstly, the exploitative social relations of health based on the present system of established modern medicine, and, secondly, the system of cultural-anthropological health representations. If the first question, focus of the book, is methodically dealt with, the second dimension, although occasionally and commendably tackled (for instance, illness seen as the result of falling out of harmony with the universe, p 14-17, or the women's inferior value as an explanation for women's lower health status, p 148, 151), would yet deserve a wider and independent consideration that the somehow narrow socio-economic perspective of the authors overshadows.

Let us stress the importance of this second aspect with the example of the exorcism practices performed by religious healers. Around these latter, symbolic sets wave together in ritualistic health practices, the sick, the sacred power, the departed, the go-between-the holy man, the enemy, the genders, etc. (Poitevin). Especially in a traditional agrarian community, health, death, disease, injury, wound, infection, healing are no natural events. Body, blood, hair, sex, menses, birth, injections, etc, are invested with far-reaching and interconnected meanings. They are socio-cultural constructs before being subject to the specific and restricted medical constructs, outcome of the particular and alien assumptions of modern medicine. We cannot take for granted that these latter will easily erase the previous constructs. On the contrary, the traditional meanings are likely to turn up the new speech in such a way as to give it a fitting place in their midst. The point at issue is here that the working of the "exploitative forces" so often rightly referred to, would still be better understood once are discovered both the autonomy and the interdependence of those two levels of analysis. (Althusser, 1970). They overlap in reality as two aggregate dimensions the cumulative effect of which is to be understood in each given social formation under consideration.

A common and easy example may illustrate this interplay. Why do rural people feel a deep and pressing urge for injections? Some traditional unconscious drives and representations (for instance, expectation of a sudden and miraculous recovery through some mysterious device: pricking and pain may act here as a substitute to the ritualistic cutting the throat of a cock) have to be explored and brought out under conscious light. Why do medical practitioners not try to scientifically demystify and reveal to their trustful clients, the quasi-religious nature of their demand, instead of promptly complying with the people's expectations, if not anticipating them, often without any medical necessity? And why do they not, as a principle, entrust this task only to the nurse care? The reasons are known. In doing so, male doctors invest themselves with this very power otherwise attributed to the local healers whose practices are no less mysterious and

knowledge no more transcending their reach and consequently calling for the same complete trust (an important message conveyed by the health education programmes, as appropriately stressed by the authors, p 185). One difference: instead of accepting free gifts, the modern practitioner will claim substantial fees taking advantage of the anxiety and faith of his client—biting again into the starvation income of the needy. In short, in the process, the traditional set of feelings and representations as well as the passive, helpless and submissive relations of health woven around the sacred healers' practice provides the rationale for the acceptance and social sanction of the exploitative practices and the overall male domination of the modern class of medical practitioners. This acquires a specific gender dimension when we remember that it is mainly women who resort to the ritualistic healers (Herzlich and Pierset, 1984).

The book keeps clear also of a second pitfall which usually consists in resorting to health services offered by voluntary agencies with technical qualities and appropriateness of which the public health care system is deprived. The main concern is here for professional performance. This is short of the political will and thrust required to cope with the remote and determinant causes of ill-health as well as with the public dimension of a national service. Each citizen, especially the deprived one, is entitled to health as a right and not as a commodity to be made available even at a lesser cost and served wrapped in humanitarian feelings.

Strategically speaking, it follows from this that health for all cannot be achieved unless it is health by all, i e, obtained as a right by the majority of all those who are kept deprived of it. As neither the public health care system as it operates nowadays nor the troups of NGOs in rural health care can be expected to secure health for all in no century, those concerned with obtaining their right share of health facilities are left with one single alternative, viz, to fight and vindicate their right. This is the right perception which upholds the whole approach.

Need for Tactical Model of Action

To the tactical question "How to go about it?", the answer is that the proposed alternative approach is firstly to be monitored from within the low ranks of the health care system, by the middle level health professionals transforming from within their concept of health and practice of health care. They are staged as the sensitive category through which defiance and innovation will arise. Why we may ask, do the authors assume that this category is potentially fit for spearheading the envisaged radical changes which will reconstruct the established health system? From their own experience? From the fact that this category of workers remaining close to the common people while being technically trained, may prove immediately operative, provided they only shift their socio-cultural allegiance from the class interests of the medical profession towards the lower sections of the rural population? But then, why do the same authors, from the last chapter, characterise these middle level workers as short of experience of village work, deprived of proper training, used only to follow orders and the least involved in a critical examination of their work?

In the fourth section, they are shown a plan of action, and equipped with pedagogical skills enabling them to raise, mobilise and train village health workers in two or three villages around their dispensaries. From where and how do they become all of a sudden motivated for investing their time, energy and thinking capacity in tasks for which, as a professional category, they could only feel shy or have aversion? And we know that as a rule such is actually the case. Before showing how motivated health workers might motivate village health workers, we would also like to know how the low-rung health workers as a category could themselves become enthused in a proportion sufficiently significan as to make them a category and not only a few individuals, initiators pioneering the envisaged alternative methodology of health practice.

Barring exceptional cases which make no use of tactical model of action for social change, one fails to realise how an individual woman from the middle rung health workers may embark alone in such attempts without at least two minimal pre-requisites. The first one is institutional backing, however loose or informal it may be, not only to support her after she has started but to secure since the inception precisely what is taken for granted, viz. the means of a radical reappraisal of her whole training and practices. To put in her hands *Helping Health Workers Learn* (Werner and Bower) is no sufficient answer: a book does not offer a supportive group. In their final inset (p 307), the authors have themselves raised the question to leave it open: does the health worker continue to spend most of her time in her dispensary or in the village? Does she want to radically transform her role? Can she do it within her present institution or should she work with another group? How can she build up support for her work and herself? Unable to visualise a definite plan for mobilising the category they address, the authors satisfy themselves with calling those concerned to chalk out for themselves their course of action.

Here comes the second prerequisite. Irrespective of the forms and nature of the 'institutional' framework, the health worker will not be able to act according to the new role she wishes to assume unless groups of villagers either raised by her or anyone else, organise themselves and through a sustained effort of cultural action develop among themselves and the population that dynamics from the bottom required to put them on the way towards what we have labelled health by the people. Following the catalytic effect of the health worker, it is this organised strength, embryo and basic element of a wider health movement, which may come to effectively bear upon the health system to force it to change in the long run. One may finally wonder whether in the scenario imagined by the book under review and the course of action to be chalked out, the leading role is not to be more plausible ascribed to the villagers' organisation. Without this organisational prerequisite, an isolated female health worker in rural areas cannot achieve much whatever the clarity of her choices; but as a health professional taking sides with such organised groups of villagers she may, for sure, work wonders. To this effect, the chapters 3 and 4 of the 4th section deserve a careful attention.

Many paramedics trained by or working in, christian institutions especially in southern states, may be able to take advantage of this book directly in English. For the many others, let us hope that translation will appear in vernacular languages to make this precious handbook actually available

to all those whom it addresses.

The authors have made a successful attempt to wirte in a clear and accessible language without compromising the necessity for health workers and health activists to master the relevant terms and facts. The presentation of the tables and graphs deserves a special mention for its clarity, careful selection, relevance and attractiveness. Many graphs may not fail to impress even illiterate readers, such as the set showing the decrease in mortality due to infectious diseases for the USA, 1900-1973, in relation to specific medical measures (p 110): one is immediately, visually convinced of the very low significance of the medical interventions in the matter. No professionally competent health activist may afford to do without this handbook. We even consider that no health worker worth the name may go without the basic knowledge imparted by this book. We wish all institutions dealing with rural health care adopt it as a basic vade-mecum for all their workers. A didactic style and the arrangement of the contents in about 35 more or less self-sufficient units, make the book easy to be used as a reference book, to be read piecemeal or utilised a la carte, according to one's daily requirements.

The authors deserve felicitations too for enlivening their technical expositions with pictures and drawings which try to give a graphic visualisation of abstract ideas and often carry the appropriate emotional import. The big size of the book (21.5 cm x 25 cm) was skillfully taken advantage of to device a well-spaced out disposition of the drawing and matter, each page being divided into two parts with short lines: this facilitates the reading and helps to grasp and memorise the matter of each paragraph.

Dalkon Shield Battle Continues

IN late January 1986, a former Dalkon Shield user suggested that the Women's Health Information Center (WHIC) was the appropriate body in Israel to organise a campaign to notify Dalkon Shield users of their right to apply for compensation for damages. The WHIC, a project of the Israeli feminist movement, consists of small group of volunteers who for several years have provided health information and education to women through a weekly open phone line, health fairs, lectures and other activities. We knew that the manufacturer of the Shield had been required by the Court in America to notify users of their right to sue, but that the company had made little or no effort to do so here. We decided, in February, to take on the job of locating Shield users. We also decided to work with an American lawyer, who could give us information and guidance and could later represent the women we located, if they so chose.

We knew that Robins claimed to have sold the Shield in Israel, but had no idea of how many were actually inserted in Israeli women. The Ministry of Health told a reporter from a local newspaper that there were none in Israel. However, in mid-February we placed a small ad in the same newspaper and over 100 women responded immediately! Some of them definitely used the Shield; others strongly suspected that this was the IUD they had once used. Daily calls poured in, and, helped by volunteers from the Feminist Center and the Rape Crisis Center, we responded by sending out information and forms, and listening to the horrifying stories of complications women experienced with the IUD.

In February and March the WHIC sent information to the press and some ten articles were published about our campaign in Hebrew, Arabic and English newspapers. We also spoke on radio and placed another small ad in a women's magazine. Women from every corner of the country-cities, villages, kibbutzim-requested help filing claims. In April we held a meeting to give potential claimants an opportunity to meet with the lawyer, ask questions and discuss problems they were having getting medical records.

Among the claimants was one who had already verified that the IUD she received at Kalpan Hospital was indeed a Dalkon Shield, and that she had been one of 500 to get a Shield as part of an experimental program. After several weeks of negotiation with officials of the Health Ministry, Kalpan Hospital and the General Health Insurance authorities, we received permission to notify these 500 women. Unfortunately half of the addresses had been lost in the hospital archives, so we were able to write to only 250, and we lost many of these women due to lack of forwarding addresses from their previous homes.

After the April 30th deadline, Kalpan Hospital suddenly FOUND the misplaced list of the other 250 women—but now it was too late to put in claims!

Meanwhile, women continued to call us even after the April 30th deadline passed. There is a definite possibility that not all Dalkon Shield users in Israel were located, due to the limited time and money that were available to us.

When women began to request their medical records they discovered: that many files had been destroyed (they seem to save files for only 7 years here); the hospitals would not cooperate with them; details were not carefully listed—only the word IUD appeared; most private doctors had no files; and some doctors were no longer alive.

Reinterpreting Homoeopathy

ch v subha rao

IF homoeopathy is to take its rightful place in the health care systems of the 21st century, it must be re-interpreted from the standpoint of dialectical materialism. Samuel Hahnemann, the celebrated founder of homoeopathy, was never so dogmatic as to rule out new interpretations. He says that natural laws cannot be capitalised or kept under the seal of human authority. People may utilise natural laws and yet may not be able to understand the crux thereof. Thus Hahnemann indirectly admits that natural laws may be more fully understood by future generations. He terms as *probably correct* his explanation of the mode of action of homoeopathic medicines. He expressly states that others can form their opinions in the matter. He prepared six editions of his magnumopus *The Organon* in his lifetime and he was constantly innovating. Nearly 150 years have elapsed since the deathof Hahnemann. It is high time somebody reinterpreted homoeopathy and surveyed medical science in general in the light of subsequent developments in philosophy and science.

In his book *Principles and Art of Cure by Homoeopathy*, Herbert Roberts tried to demonstrate that homoeopathy was based on the bedrock of natural laws. More effort on those lines is required now. In the Soviet Union, philosophers and medical scientists are trying to develop modern marxist concepts of life, health and disease. Hahnemann's role in medicine may be compared to that of Hegel in philosophy. Both were philosophical idealists. The rational kernel of their teaching was enveloped by a mystical shell. Marx accepted Hegelian dialectics but rejected idealism. Similarly, it should be possible to separate homoeopathic therapeutics from its idealist shell.

During Hahnemann's lifetime (1755-1843) there were hardly any scientists who were consciously and consistently materialistic in their world-outlook. It is, therefore, not surprising that Hahnemann was deeply influenced by and deeply dissatisfatied with idealist philosophers. He was a deist and a religious free-thinker. He wrote: "The ever-beneficent Godhead animating the infinite universe dwells in us also".[1] He felt attracted by philosophy, but the philosophers and their works offered him little satisfaction. He said: "Philosophy is not only the highest of all sciences, it is also the basis and the fundamentals of all others. No science can exist without philosophy, for without its help it falls to the level of a handicraft or at any rate of a subsidiary subject. This is true above all of medicine" (Haehl).

Hahnemann's biographer Richard Haehl says: "What particular philosophic system he supported is not discernible from his writings or his letters. It seems very questionable whether he definitely accepted any special system. He should rather be regarded as an eclectic who selected from each system the best for his own view of life and the world. From his schooldays onwards he had followed Descartes, Spinoza and Leibnitz (whose systems dominated the schools of the time) and then proceeded to vitalism and to the naturalism of Schelling and Hegel. *He advanced beyond this to spiritualism* and for a time lost his way in occultism. In temperment and development, both as man and as physician, he was a strong opponent of materialism. With all his emphasis on scientific exactitude and empiric certainty as the starting point of his therapeutic reform he rejected materialism equally as an outlook on life and as a fundament of his new theory:... But, on the other hand, he took for his own purposes the basic thoughts of doubt from materialism. He took up a definitely conscious standpoint from facts of experience and rejected every philosophic speculation which did not agree with the latter. For this reason Kant was too impracticably abstract for him and not clear enough in his manner of presentation. Of Plato he complains that he is only valuable when he speaks intelligibly and expressively. His criticism of the philosophers after Kant is that they wrote 'even more mystically' than Kant, that they composed too freely in fancy and that that they had therefore not kept to the bounds of experience" (Haehl).

For Hahnemann, theory was of minor importance (Haehl). Engels, on the other hand, attaches great importance to theory. "However great one's contempt for all theoretical thought, nevertheless one cannot bring two natural facts into relation with each other, or understand the connection existing between them, without theoretical thought. The only question is whether one's thinking is correct or not, and contempt of theory is evidently the most certain way to think naturalistically, and therefore incorrectly. But, according to an old and well-known dialectical law, incorrect thinking, carried to its logical conclusion, inevitably arrives at the opposite of its point of departure. Hence, the empirical contempt for dialectics is punished by some of the most sober empiricists being led into the most barren of all superstitions, into modern spiritualism" (Engels, 1982).

Let us now turn to Hahnemann's concept of vital force. "In the healthy condition of man, the spiritual vital force (autocracy) the Dynamis that animates the material body (organism), rules with unbounded sway, and retains all parts of the organism in admirable, harmonious, vital operation as regards both sensations and functions... The material organism without the vital force is capable of no sensation, no function, no self-preservation; it derives all sensations and performs all the functions of life solely by means of the immaterial being (the vital principle) which animates the material organism in health and in disease" (Haehl).

On the concept of vital force Engels says: "If by this (vital force) is meant that the form of motion in the organic body is different from the mechanical, physical, or chemical form and contains them all sublated in itself, then it is a very lax manner of expression, and especially so because the force-presupposing transference of motion appears here as something pumped into the organism from outside, not as inherent in it and inseparable from it, and therefore this vital force has been the last refuge of all supernaturalists" (Engels, 1982). And again: "*The Organism is certainly the higher unity which within itself unites mechanics, physics, and*

chemistry into a whole (emphasis original) where the trinity can no longer be separated. In the organism, mechanical motion is effected directly by physical and chemical change, in the form of nutrition, respiration, secretion, etc., just as much as pure muscular movement." Thus it may be necessary to modify or even altogether abandon some of the concepts of Hahnemann.

All this, however, should not detract from the merits of homoeopathy which are many and solid. The patient is treated on the basis of 'totality of symptoms'. The uniqueness of each patient is recognised. Permanent cures are accomplished in the gentlest manner possible. The pills are sweet and incredibly cheap. The efficacy of homoeopathic remedies is beyond question. Indeed, allopathic treatment is said to be absolutely necessary only in a new cases. Homoeopathy provides prophylactics as it did when encephalities was taking a heavy toll of lives of children in our country.

We are chasing the mirage of Health for All by 2000 AD. In a rational world there will of course be great emphasis on prevention of disease. It will be a non-violent, nuclear-weapon-free world. It will be free from pollution. People will consume unadulterated and uncontaminated foods free from toxic food additives. There will be excellent sanitary arrangements. Everyone will get food, clothing and housing. Occupational hazards will be minimised. Consumption of narcotics, alcoholic liquors, cigarettes etc, will be drastically reduced. There will be less stress and fewer deaths due to accidents. Nowadays goods are being produced, advertised and sold without the slightest regard for their harmful effects on the consumers. The elimination of profit motive in production is a pre-condition to achieve the goal of Health for All.

If the masses are the real makers of history, it follows that the above goal cannot be reached without a people's movement. In India, progressive forces have been demanding the nationalisation of drug industry and rationalisation of drug policy. They have not met with much success. Drugs constitute one important area of multinational swindling. Our dependence on transnational drug manufactures and on drugs themselves must be reduced. Right now state aid to systems like homoeopathy, ayurveda, and unani is just nominal. It is nobody's case that the baby should be thrown away along with bathwater. The dialectical method should be applied to the facts of medical science and health care. Such a comprehensive critique will enable us to see things in proper perspective and to assign to each system the role it deserves. The quest for truth and for cures must be the motive of such an inquiry and neither passion nor prejudice nor private profit should be allowed to hinder it. The reinterpretation of homoeopathy will form part of such a critique.

Much basic research has to be done if homoeopathy is to gain wider acceptability. For instance the mode of action of homoeopathic remedies has not been satisfactorily explained so far. The materia medica can and must be enriched. Potentisation of drugs can perhaps be explained in terms of the law of transformation of quantity into quality. The law of cure 'Similia Similibus Curantur' may have something to do with the law of negation of negation. If sufficient funds and talents are pumped into homoeopathy, it may develop into the healing system *par excellence* of the future.

ADVERSE EFFECTS

Women and the Pharmaceutical Industry

Edited by Kathleen McDonnell

Medical remedies which are inappropriate, wasteful and sometimes simply downright dangerous, overload the world. Many are targetted specifically at women. ADVERSE EFFECTS sets out to examine, in a global context, how women are frequently exploited and injured by drugs. Articles from India, the Philippines, Canada, the Netherlands and USA illustrate how women are successfully organising themselves to fight this ill-treatment and manipulation.

Part I - WOMEN AS DRUG CONSUMERS
Articles on EP drugs, hormone treatments, DES and mood modifiers.

Part II - PHARMACEUTICALS AND FAMILY PLANNING
Articles on Depo-Provera, the rise and fall of the IUD, and the fight to keep injectables out of India.

Part III - TAKING BACK CONTROL
Two articles examine some of the efforts being made to challenge the power of the multinational pharmaceutical industry.

ADVERSE EFFECTS: ISBN 967-9973-17-4 1986 © IOCU 217 pages 5½" × 8½" US$7.95 pb.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a radical or Marxist perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions in a neat handwriting on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (for issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

The Hungry Sparrow

The hungry sparrow
flew about in search of grain.
The grain was trapped in the wood of the grinder.
The sparrow said to the carpenter:
Brother carpenter, brother carpenter, the grain
is locked in the grinder.
What shall I eat?
How shall I cope with my hunger?
What shall I carry to another clime?

The carpenter split the grinder;
Out flew the grain.
and the sparrow after the grain.
But the wicked grain lodged in the royal
granary, guarded by a sentry.
Said the sparrow to the sentry:
Brother sentry, brother sentry, the grain
is lodged in the granary.
What shall I eat?
What shall I eat?

The sentry took the matter to the minister.
The minister to the monarch.
The monarch summoned the commander-in-chief
Who appointed a magistrate to study the case.
The magistrate read through reams of law,
and argued back and forth:
Why, in the first place, the magistrate wondered,
did the sparrow have to be hungry?
At any rate, if hungry she was,
Why did she have to pursue the grain?
The grain that of its own desire lodged
in the royal granary.

News spread rapidly.
The papers carried it end to end:
'Sparrow versus the grain' was the cry everywhere.
It was plain that
the sparrow was hungry without rhyme or reason.
Her guilt was beyond doubt.
The hungry sparrow was shot.

Law, Medicine and the People

THE purpose of law, it is said, is to 'regulate' human activities in a society and the medical world concerns itself with "improvement in physical and mental health of the people and the prevention, diagnosis and treatment of illness". It is, therefore, quite natural that laws relating to the medical world need to be examined and modified/rectified from time to time in relation to their impact on the society and people they aim to regulate.

The Indian legal system and laws, in particular those related to medical practices etc., are borrowed to a great extent from the British system. It is pertinent to compare their impact on the people(s) in terms of their meaningfulness to them. It would be both cumbersome and meaningless to make a comparison of each law (related to medicine) and examine its 'regulatory impact' on the society. Besides, there are laws relating to medical practice that are only remotely concerned with the general public and are, therefore, not of consequence here. In fact it might serve to consider here the different entities and their functions and the laws pertaining to them.

Doctors and Laws

Medical practioners must 'register' before they can practice and collect fees for their advice and registration is subject to minimum standards of qualification. Under the Medical Act these responsibilities are given to respective Medical Councils. These Medical Councils are also empowered by the act to cancel the registration of a medical practitioner from the Medical Register if there is "serious professional misconduct" and there is a Medical Disciplinary Committee set up for this purpose. In UK several registrations have been erased either because it is "necessary for the protection of members of the public or in the best interest of the person suspended." And there is usually a very meaningful debate on the issue in medical journals, which itself acts as a deterrent for others. Such erasure of registration of medical practioner is almost absent so far as the Medical Council of India is concerned. However, the absence of erasure need not be construed to mean that things are above board in India. Adultery, improper association, negligence, and advertising are some of the issues on which registrations can be erased and many of our practitioners violate at least some of these and yet the MCI does not seem to be stirred enough to take action.

To take another example, according to the Act: "Nothing in the act shall extend or be construed to extend to prejudice or in any way affect the lawful occupation, trade or business of chemists and druggist and dentist or the rights, privileges or employment of duly licensed apothecaries so far as they extend to selling, compounding or dispensing medicines". Yet it is almost a universal practice for general practitioners in India to dispense drugs and charge for the same. Neither the MCI not the state have taken any action on this.

Further, "It is the duty of every registered practioner to bring to bear upon all his professional activities that standard of skill and knowledge which is to be expected of a practitioner of his experience and status and of comparable standing to him. It is also his duty to exercise reasonable care in his treatment of a patient. If the failure to exercise the necessary degree of skill or care results in injury to the patient, he will have a right of action for damages. Whether reasonable skill or care has been exercised in a particular case is a matter which has to be considered in relation to the facts of each case." No branch of the law affects the practice of medicine more strongly than the law of tort (civil wrong) under which negligence is perhaps the most talked about.

The glycerol tragedy in the J J Group of Hospitals has highlighted the issue of negligence. There can be no doubt about the fact that there was negligence on the part of everyone including the doctors of the hospital and yet is it not strange that the MCI has chosen to remain silent on the issue? It is in circumstances such as these where the ethics and rules enforcing bodies such as the MCI refrain from acting that the absence of people's participation in such matters become evident. What does one do when professional bodies fail to act?

Yet another example is that of the Bhopal disaster where the gas-affected people were 'denied' the antidote sodium thiosulfate for reasons that are still unclear today. Doctors' obligation, the Council's obligation and the state's obligation are evident by their absence.

Another issue that needs to be discussed here is the one related to informed consent. "A doctor has no right to do anything to a patient without his consent except in the case of emergency when he must exercise his discretion. The securing of a signature to a consent should not be allowed to become an end in itself. The most important aspect of any procedure must always be the duty to explain to the patient or relative the nature and the purpose of the proposed operation and thus to obtain a fully informed consent. In our country this should be even more important (though admittedly also more difficult) since there is so much illiteracy and lack of information. But it is common knowledge (though difficult to prove) that informed consent is reduced to a mere signature-obtaining exercise. The matter becomes even more serious when, to meet the family planning targets, healthy women and men are subjected to sterilisation operations.

Drugs are another entity subject to standards. Our drug laws are very similar to the British ones. An additional regulation in India is the Drug Price Control Order, which sets norms for prices of drugs. Despite

this, unlike in UK, the bulk of 40,000 to 60,000 formulations put into the market by over 9,000 manufacturers, are irrational, useless or even hazardous in some cases. A significant number of them are sub-standard. Doctors' prescriptions are often found to contain superfluous and unnecessary drug formulations, evidently to favour the drug companies' representatives. One report indicates that in Tanzania, there is one drug company representative for every four doctors (see Mukarram Bhagat's *Aspects of Drug Industry in India'*). In India, with 9,000 drug companies, the situation is very much the same. (In UK, the ratio is 1:20). Clearly the Indian patient pays a great deal more for medicine and gets much less value for it. Laws and the legal system need to take cognisance of this and ensure regulatory mechanisms to remedy this situation. What is more, the Bangladesh drug policy has already unequivocally demonstrated that the expenditure on medicine can be reduced and more 'value' made available to the patients and has also proved to be sustainable.

Health Services and Law

If there is similarity in the British and Indian laws in respect of drugs and registrations of doctors, the hospital services policy is different. In UK, under the National Health Services Act 1946, comprehensive health services are made available to the people. This includes a scheme of social insurance, and covers an overwhelming populace of the country. In India there is no comparable legislation and the state health sector incorporates the medical services including CGSS and ESIS. Indeed there are public hospitals and dispensaries which are supposed to deliver medical services free or at very nominal fees but in effect are found wanting. There are no minimal standards clearly specified for commissioning of hospitals or dispensaries and it is not unusual to find Primary Health Centres being reduced to the structure of bricks and mortar. Hence even the Health Policy promises to have at least one PHC for every 30,000 population, this goal is not attained and at times even when there is a PHC existing, it could hardly be functioning. Comically hotels and restaurants of some cities in India are graded according to the services they make available but not the hospitals.

The quality and quantity of health/medical care made available to the people is hopelessly inadequate and with the paucity of resources it is clearly evident that radical and pragmatic legislative and policy approaches are necessary. Strangely it is the countries where health/medical care is of a high standard, which are clamouring for 'radical' changes in their system to be even more effective e g, in March 1987, the British Medical Association recommended that the government introduce a 'no-fault' compensation scheme based on the Swedish model. Diana Brahams (*Lancet*, January 2/9, 1986, p 43) explains "In my view the term 'no fault' is inaccurate; in truth the scheme provides compensation without apportioning blame for unexpected adverse results arising from medical treatment in which error was an important factor. A failure to act, or to act in time, may also be compensable."

It is interesting to compare medical malpractice perspective in US and UK (where consumer awareness is high) before one takes stock of the situation in India. In the United States (as everyone knows) the suits pertaining to medical malpractice are far more frequent than those in United Kingdom. Lois Quam *et al* of the Centre for Socio-Legal Studies, Oxford, have reported in an excellent study in this respect (*BMJ*, vol 294, 1987, pp 1529-1532 and vol 294, 1987 pp 1597-1600) that "the reasons for this are related to American health care and social security systems. "Relative to United Kingdom, there are fewer barriers of access to the courts." "The differences between the National Health Service and American health services are gross and well recognised. The close relation between the cash nexus of private practice and high rates of litigation in the USA is less understood." Patients who are paid directly for their health care, through a mixture of insurance premiums and contributions out of pocket, seem more likely to feel aggrieved when treatment fails. Moreover, litigation is fuelled by the sheer cost of extra care after an iatrogenic injury or treatment.

In principle the National Health Service (UK) seems likely to reduce claims in at least four ways: There is no direct cost to the patient for extra medical care to remedy injury; access to care is guaranteed throughout life; there is no direct financial relation between doctors and patients; and the system of referrals restrains specialists while encouraging loyality between patients and their general practioners."

It is important to note that in both the countries, there is adequate provision (monetary or by services) for medical and nursing care for the remainder of life. In our country medical and health care is grossly inadequate and despite a number of medical malpractices there is hardly any litigation or effort to redress injustice caused. Even when there is litigation, the odds are heavily pitted against the patient in more ways than one: (i) there is a strong nexus amongst doctors to 'protect' one another in the event of a case in the court; (ii) patient record is not available to the patient (unlike in Sweden) for proper presentation of the case; (iii) and lastly the cases drag on (very often) for such an extraordinary length of time that most people find it beyond their means to 'sustain' litigation. Although the Legal Services Authority Bill has been passed under which free legal services are made a statutory right the bill has grave limitations and is self-defeating. That it does not provide for mass participation and nor does it attempt to provide relief beyond the monetary (see Krishna Iyer's Comment in *From the Lawyer's Collective*, November 1987). Thus, legal provisions cannot be an end in themselves. While legislation provides for the possibility of ensuring justice without prejudice both its content and form are limited to the socio-political context of particular societies. Its extension and implementation is a consequence of people's movements.

Medical Malpractices and Law

mihir desai

Although medical negligence claims are an off-shoot of industrial capitalism, given the circumstances, the existing negligence law can serve a useful purpose in imposing a certain accountability on the part of the doctors and providing redressall for injuries. The legislation should thus be seen not just as a reflection of bourgeois ideology but also as a bourgeois democratic right which requires to be extended and expanded.

MEDICAL negligence litigation has in the past too decades risen sharply in England and the US. Especially in the US it has reached such a stage that a strong and active lobby has come up against this. It has also led to the increasing practice of 'defensive medicine' and a rise in doctors' insurance rates. In India, of course, there is no corresponding trend. The Indian law on this aspect, however, slavishly follows the British and the American law. These trends therefore become very relevant in India not only for gauging the potentialities of this type of litigation in India but also to highlight the positive and negative aspects of this system. Though the medical systems in the US and in UK are very different—complete privatisation in the one while state health services in the another—the law is virtually identical. These trends cannot be viewed in a vacuum but only in the context of the socio-economic aspects of medical-malpractice liability and the reasons why its development has been stagnant in India.

Medical negligence litigation is a response to the following types of questions.

What are the rights of patients vis-a-vis the doctors and hospital?

What if the doctor wrongly diagnoses a disease?

What is the level of competence expected of a doctor?

Does a doctor have to take the consent of the patient before an operation?

If many doctors have handled a patient which of them is ultimately liable?

The common issue in all this is the patient's allegation that the doctor has been negligent.

Negligence and Torts

Medical negligence is a branch of the law of negligence which in turn is a branch of the law of Torts. The Tort law is not based on any act of Parliament. It is mainly a judge-made law developing over the years through changing judicial decisions. It is not possible to define Torts but broadly speaking tort is a wrong done by one person to another for which the law provides a remedy. The idea is to monetarily compensate the victim rather than punish the offender—as would be the case in criminal law. It includes disparate events such as a car accident, injuries due to emission of poisonous gas, doctor's negligence causing death of a patient, defamation of a person, compensation for injuries suffered by a wife at the hands of her husband, etc. The motives of the offender are not very relevant. The focus is on the victim.

A person is said to be negligent when s/he acts without due care in regard to the harmful consequences of his/her action. When we say that a person has been negligent we are saying that s/he acted in a way that s/he ought not to have acted. This assumes that we know how s/he ought to have acted. The way in which we consider that s/he ought to have acted is the norm or standard which entitles us to condemn the person for being negligent when s/he fails to comply with the standard.

The tort of negligence is made up of three components:

(1) A duty or obligation recognised by the law requiring the person to comply with certain standards of conduct for the protection of others against unreasonable risks. Initially charitable hospitals used to claim that they could not be held negligent as they had no duty to take care of patients since they were not charging them. Now of course the courts always disregard such defences.

(2) A failure on the part of the person to conform to the standard required—what is known as a 'breach of duty'.

(3) A reasonably close causal connection between the conduct and the resulting injuries.

(4) Actual loss or damage resulting to the other.

So, negligence ultimately is a matter of risk—that is to say, of recognisable danger or injury. Persons are supposed to meet with certain standards of conduct. This standard is supposedly based on what society demands of its members, rather than upon the actor's personal morality. A failure to conform to the standard is negligence even if it is due to clumsiness, forgetful nature, an excitable temperment or even sheer ignorance. In other words, the state requires of a person not to be awkward or a fool.

In negligence, the actor does not desire to bring about the consequences which follow nor does s/he know that they are certain to occur, or believe that they will. There is merely a risk of such consequences sufficiently great for a 'reasonable person' in his/her position to anticipate them and to guard against them. Risk can be defined as a danger, which is apparent or should be apparent, to one in the position of the actor.

Nearly all human acts, of course, carry some recognisable or remote possibility of harm to another. No person so much rides a horse without some chance of a runaway nor does any surgeon perform an operation without some chance of himself suffering a heart attack and messing up the operation. These are of course, 'unavoidable accidents' for which there is no liability. As the gravity of the possible harm increases, the apparent likelihood of its occurrence needs be correspondingly less to generate a duty of precaution. Thus the standard of conduct which is the basis of the law of negligence is normally determined upon a risk-benefit form of analysis by balancing the risk in the light of the 'social value' of the interest threatened, and the probability and the extent of the harm, against the value of the interest which the actor is seeking to protect and the expedience of the course pursued.

Professional Negligence

Uptil now what we have talked about is the minimum standard below which the individual is not permitted to fall. But if a person in fact has knowledge, skill or even intelligence superior to that of the ordinary person, the law will demand of that person's conduct be consistent with it. Professional persons are not only required to exercise reasonable care in what they do, but also a standard minimum of special knowledge and ability.

Let us look at how in practical situations the law applies to doctors. A doctor may, of course, contract to cure a patient, or to accomplish a particular result, in which case he may be liable for breach of contract. This is not, however, what generally happens. In the absence of such an express agreement, the doctor does not warrant or insure a correct diagnosis or a successful course of treatment and a doctor will not be liable for an honest mistake of judgment where the proper course is open to reasonable doubt. But by undertaking to render medical services, even though gratuitously, a doctor will evidently be understood to hold himself out as having standard professional skill and knowledge. The formula which is used is that the doctor must have and use the knowledge, skill and care ordinarily possessed and employed by members of the profession in good standing, and a doctor will be liable if harm results because he does not have them. Sometimes this is called the skill of the 'average' member of the profession, but this is clearly misleading. Since only those in good professional standing are to be considered; and of this it is not the middle but the minimum common skill which is to be looked to. If the doctor claims to have greater skill than this, as when the doctor holds himself out as a specialist, the standard has to be modified accordingly.

Of course, there are areas in which even experts differ. Where there are different schools of medical thought and alternative methods of acceptable treatment, it is held that the dispute cannot be settled by the law and the doctor is entitled to be judged according to the facts of the school the doctor prefers to follow. This does not mean that any quack or a crackpot can let himself be known as a 'school' and so apply his individual ideas without liability. A 'school' must be a recognised one within definite principles and it must be the line of thought of a respectable minority of the profession. In addition there are minimum requirements of skill and knowledge, which any one who holds himself out as competent to treat human ailments is required to have, regardless of his personal views on medical subjects.

Since judges/juries are essentially lay people, they are held to be normally incompetent to pass judgment on questions of medical science or technique and so only in certain types of cases findings of negligence are given in the absence of expert medical evidence. Normal reluctance of doctors to testify against co-professionals came in the way in US and UK and is likely to be a big hurdle even in India. Now of course, in US and UK more and more doctors came forward to give evidence on behalf of patients. Also, where the matter is regarded as within common knowledge of the lay people, as when the surgeon saws off the wrong leg or where injury is caused to a part of the body not within the operative field, the judges often infer negligence without expert evidence.

The cumulative effect of all this is that the standard of conduct becomes one of 'good medical practice' i e, what is customary and usual in the profession.

This, of course, gives medical profession a privilege denied to others, of setting their own legal standards of conduct merely by adopting their own practices, except in certain cases like in the cases of sponges left in the patient's abdomen after an operation where the task of keeping track of them has been delegated by the surgeon to a nurse. Though this was and is still a routine practice, the doctor was found to be negligent.

Some Specific Trends

In one of the earliest decided cases, in 1767, an English court felt that the surgeon was liable as he had acted contrary to the known rule and usage of surgeons. What happens if the patient is injured because of the omission to carry out an available test, which is not generally conducted by doctors for such patients? In 1974 an American Appeal Court was faced with this issue. Barbara Helling suffered from primary open angle glaucoma. This is a condition of eye where there is an interference in which nourishing fluids flow out of the eye. There can be a resultant loss of vision. The disease has few symptoms and in the absence of 'pressure test', is often undetected till irreversible damage is done.

Helling contacted two opthamologists—Carey and Laughlin—at that time believing that she was suffering from myopia (shortsightedness). From 1959 to 1968 she consulted these doctors, who fitted contact lenses and believed that irritation caused in her eyes was because of complications associated with the lenses. For the first time in 1968 they tested the patient's eye pressure and field of vision. This indicated that she had glaucoma. By that time the patient, who was 32, had essentially lost her peripheral vision and her central vision was reduced. She filed a case for damages.

The doctors argued and proved that the standard of the profession did not require the giving of routine pressure test to persons under the age of 40 as the incidence of glaucoma is 1 out 25,000 persons under the age of 40. They argued that since they had acted in accordance with the standard practice of the profession they had acted with reasonable prudence. The court, however disregarded this defence. The judges held: "In most cases reasonable prudence is in fact common prudence, but strictly it is never its measure. A whole calling may have unduly lagged in the adoption of new and available devices. Courts must in the end say what is required: there are precautions so imperative that even their universal disregard will not excuse their omission."

The court felt that despite the fact that a pressure test was not used generally by opthalmologists, the doctors ought to have used it. Barbara received compensation.

The importance of the case lies in the fact that the standard of care required of the doctors is widened. Normally of course the standard adopted in the profession would be acceptable as the standard required of each doctor. But this case for the first time obliged doctors to conduct certain known tests even if they were not being conducted in the profession generally.

This case created a storm in the USA. Attempts were made through courts and legislature to change the law laid down by the case, but ultimately they have proved to be futile. However, the application of this case is only confined to

narrow field of possibilities and that of 'general practice' within profession is still widely applied.

Hospital Liability

A question of immense significance is whether a hospital can be made to pay for negligence of doctors, nurses and other staff. This is an issue of great importance in India. Many times it is not possible to point out the person whose negligence led to injury. Take the example of a patient who is given saline by a number of doctors and nurses from time to time. A particular needle may not be sterilised causing gangrene. It is not possible to know who exactly was negligent. Can one then sue the hospital? Or many times it may so happen that the negligent staff member does not have means to pay. Can one sue the hospital and recover?

The most important American case on this point was Darling vs Charleston Community Memorial Hospital decided in 1966. In November 1960, Darling, 18 years old, broke his leg while playing college football. He was taken to emergency ward of Charleston Hospital and treated by Dr. Meroander, who applied traction and placed the leg in a plaster cast. Soon after, Darling was in great pain and his toes which protruded from the cast, became swollen and dark in colour. His condition kept on worsening and ultimately the leg had to be amputated.

As to the question whether there was negligence or not, the court held that the nurses had not checked sufficiently, and as frequently as necessary, the blood circulation in the leg. Skilled nurses would have promptly recognised the condition, and would have known that they would have become irreversible in a matter of hours.

The question was whether the hospital was liable. The judges held: "The conception that the hospital does not undertake to treat the patient, does not undertake to act through its doctors and patients, but undertakes instead simply to procure them upon their own responsibility, no longer reflects the fact. The present day hospitals, as their manner of operation plainly demonstrates, do far more than furnish facilities for treatment. They regularly employ on a salary basis a large staff of physicians, nurses and interns, as well as administrative and manual workers, and they charge patients for medical care and treatment, collecting for such services, if necessary, by legal action. Certainly the person who avails himself of hospital facilities expects that the hospital will attempt to cure him not that the nurses and other employees will act on their own responsibility". The hospital was made to pay damages.

The Darling case became a landmark decision in medical malpractice claims as it places a direct responsibility on the hospital for the maintenance of an acceptable standard of care for patients. Subseqently, the scope of even this decision has been widened and charitable hospitals have also been held to be responsible.

Is the hospital liable if the patient's infection is traced to blood products supplied during his operation? In a 1970 Illinois state case, the hospital was held to be strictly liable for supplying contaminated blood. A hospital will also be liable for negligence of any honorary doctors or specialists it calls but not for private doctors called by the patients themselves. Hospitals, in same case have been held guilty even when its employees have acted in direct contradiction of the hospitals' instructions or prohibitions causing injury.

Strict Locality Rule

The standard of care expected of doctors is generally speaking that prevalent in the profession. They are not only required to perform tests generally performed, but also to be informed sufficiently about the new developments in the field.

One of the most debated issues in the US and UK arose out of a presumption that the rural and small time practitioners would be less adequately informed and equipped than their big city colleagues. To adjust to this the courts came out with a theory that there could not be any national standard of care but the standard varies from locality to locality. They applied the strict locality rule which meant that the standard of care expected of doctors depended on the general standard of that particular locality. However, in recent times this rule has been given up and national standard applied on the basis that "new techniques and discoveries are available to all doctors within a short period of time through medical journals, closed circuit television, special radio networks for doctors, tape recorded digests of medical literature and current correspondence course".

This situation is prevalent only in developed capitalist countries. In backward countries like India with uneven development, it is very likely that when cases come up, the strict locality rule will be applied.

Res Ipsa-Loquitor

Ultimately it is for the patient to prove that it was negligence which caused her/his injuries. It many times becomes difficult to do so for varied reasons like information hiding by the doctors, etc. What happens in some cases, however, is that after presenting all evidence, though directly negligence is not proved, it is still pretty obvious that the patient could not have suffered injuries except through negligence. In such cases the legal doctrine of *'Res Ipsa Loquitor'* or 'the thing speaks for itself' is applied. Negligence is presumed to have been proved and the doctors held liable.

In a case decided in an American court in 1975, a patient Anderson was admitted to hospital for a back operation. During the operation, the tip or cup of a forcep like instrument (angulated rongekur) broke off while it was being manipulated in the patient's spinal chord. It could not be recovered and the patient suffered permanent injury. Anderson sued the doctor, the hospital, the manufacturer and the distributor. Each tried to push the blame on the other and it could not be proved as to whose negligence had led to this complication. It was not established whether the rongekur broke because of manufacturing defect, certain problems during transit or due to the doctor's negligence. If it was merely a case of determining negligence from amongst the hospital staff and doctors then even without establishing who exactly was negligent, the hospital could have been saddled with damages. Here of course, the hospital was saying that it was not the neglect of staff or doctors which caused the rongekur to break but that of the manufacturer or dealer.

It was just not possible to establish what caused the breakage. The court, however, came to the rescue of the patient and observed, "In the type of case we consider here, where an unconscious or helpless patient suffers an admitted mishap not reasonably foreseeable and unrelated to the

scope of surgery (such as cases in which foreign objects are left in the body of the patient), those who had custody of the patient, and who owe him a duty of care as to medical treatment, or not to furnish a defective instrument for use in such treatment can be called to account for their default. They must prove their unculpability or else risk liabilities for injuries suffered". All of them were held jointly liable.

The doctrine of *Res Ipsa Loquitor* has been extensively used in 'swab cases' where after the operation, an instrument is left inside the patient's body. It has also been used for other types of cases—for instance in the Canadian case of MacDonald vs York County Hospital Corporation, the patient was admitted for treatment of fractured ankle and left with an amputated leg. Heavy damages were awarded to MacDonald despite there being no direct proof of negligence.

Misdiagnosis

A liability will be imposed when the doctor fails to conduct tests which a competent practitioner would have considered appropriate or when the doctor fails to diagnose a condition which would have been spotted by a competent practitioner. In Langley's case the patient had returned from East Africa shortly before the development of symptoms. The general practitioner failed to diagnose malaria and this was considered as negligence. Similarly in Tuffil's case the patient had spent many years in a tropical climate, the doctor failed to diagnose ameobic dysentry which proved fatal. This failure to diagnose was held to be negligence.

A question which arises is whether a new doctor would have the same responsibility as a seasoned doctor? The law makes no distinction in this regard. In Wilsher vs Essex Area Health Authority, the patient had been born prematurely and had been admitted to a special unit where extra oxygen was administered to him over a long period. His sight was badly affected as a result of a junior doctor's failure to monitor properly the supply of oxygen. The hospital was held to be liable.

In many cases it is a part of the duty of the doctors and nurses to predict that the patients may damage themselves as a result of their medical condition. For instance in one case the patient had been admitted to hospital after a drug overdose. Although he had known suicidal tendencies he was not kept under constant observation and he climbed on the hospital roof and fell incurring injuries, while the two nurses on duty were out of the ward. He was awarded damages of £ 19,000.

Informed Consent

One of the most rapidly growing medical malpractice litigation is in the areas of 'informed consent'. This concerns the duty of physician or surgeon to inform the patients of the risk involved in treatment or surgery.

The principle behind this is the classical bourgeois democratic ideal of individual autonomy, i e, that every person has a right to determine what will be done to her own body and the right to have bodily integrity protected against invasion by others. Only in certain narrowly defined circumstances can this integrity be compromised without the individual's consent.

Surgeons and other doctors have to provide their patients sufficient information to permit the patient to make an informed and intelligent decision on whether to submit to a proposed course of treatment or surgery. So, even if a procedure is skillfully performed, the doctor may nevertheless be liable for an adverse consequence about which the patient was not adequately informed. Of course, the patient has to show a causal link between the non-disclosure and her injury by proving that she would not have undergone the treatment if she had known the risk of harm that in fact occurred. The courts believe that all patients in retrospect would say this and so even here they have evolved the criteria of 'reasonable patient', i e, whether this hypothetical patient in the actual patient's place would have withheld consent to the treatment had the material risks been disclosed. This, of course, is problematic because the individual patient's characteristics are totally ignored. Slowly, the courts in US are trying to incorporate even this subjective factor.

What risks have to be disclosed? All the material risks, i e, the nature of pertinent ailment, the risks of proposed treatment, including the risks of failing to undergo treatment, have to be disclosed. Even if the risk is a remote possibility it should be disclosed. However, unexpected risks may not be communicated. For instance, in an American case a patient suffered cardiac arrest during amniocentesis. There were no prior documented cases like this. The doctor was not held to be negligent.

Even otherwise there are cases where the risk disclosure may be precluded by an emergency situation or the patient's incapacity. In fact in the US all states have passed what are called 'Good Samaritan Laws' aimed at protecting doctors giving emergency roadside treatment.

The disputed issue is whether for the benefit of the patient, the doctor can withhold information from them. This happens many times when doctors feel that the patient will suffer mental shock or nervous breakdown if the risk is communicated. Such withholding is called 'theraupeutic privileges'. But there is another school which believes that all information should be disclosed so that the patient can make up her/his mind in the light of all the circumstances. The courts are divided in this point.

A problem which has not arisen in the western countries but which can arise in India is if the patient is conscious and does not consent to a treatment which is necessary to save her/his life. Can forcible treatment be justified? In most of the western countries suicide is no longer a crime and so doctors cannot forcibly treat anyone. In India, of course, this question is likely to cause some problems.

The case of minors also raises a perplexing problem. Since minors are considered by law incapable of giving consent the parents' consent has to be obtained. But what happens if a minor who is of understanding age gives instruction contrary to that of the parents? In one English case, a school girl aged 15 wanted an abortion but the parents refused to grant permission. The court held that the girl was entitled to abortion as she was capable of understanding its implications.

Nowadays, at least before surgery, a patient is normally required to sign a consent form. But the patient can still prove

that no consent or informed consent was taken and the doctor will then be liable to pay damages.

Indian Cases

In spite of making a detailed survey, the writer could find only three reported cases on medical negligence in India.

(1) The first case was decided by the Lahore High Court in 1935. R N Rao, a lawyer, suffered from high fever and sores on his face. Dr Whitamore, the Civil Surgeon, treated him. He diagnosed the disease as syphillis and gave injection of Sulphatab. Later Dr Rao suffered from gangrene and had to have his fingers amputated. His eyesight was affected and he lost his strength. He never had any syphyllis and he was informed that he had contacted peripheral nueritis because of a mistaken injection of arsenic.

The court, however, did not find the doctor guilty. The reason given was that though the diagnosis was wrong specific carelessness was not proved. The court adopted a reasoning which would be totally unacceptable today. It did not go into the question as to whether the doctor had performed the required tests before concluding that there was syphllis. Neither did it try to a answer the question as to what caused the gangrene.

(2) The second case was one decided by the Supreme Court in 1969. Anand met with an accident on the beach at Palshet in Maharashtra which resulted in the fracture of the femur of his left leg. The only treatment the local physician gave was to tie wooden planks on his legs for immobilisation. The follwing day he advised removing Anand to Poona for treatment. He also substituted splints for the planks. After that, in a taxi, Anand was shifted to Poona. Dr Joshi got him screened and found that he needed pin traction. He was then taken to Dr Joshi's hospital. Dr Joshi asked his assistant to give Anand two injections of morphia and hyoscine HB at ½ hour interval. Dr Irani gave only one injection. Anand was then taken to the X-ray room, and after taking two X-rays removed to the operation room. After about ½ hour when the treatment was over, he was shifted to the room he was allotted. On an assurance given by Dr Joshi that Anand would be out of the effect of morphia in 1½ hours, Anand's father went back to his village. Anand's mother remained with him. After about an hour she found that Anand was having difficulty in breathing and was coughing. The doctors were called, Dr Irani, Dr Joshi's assistant gave emergency treatment upto 9.00 pm when the boy died. Dr Joshi issued a certificate saying that Anand had died of fat embolism.

Dr Joshi was sued. Anand's father contended that Dr Joshi did not perform the essential preliminary examination of the boy before starting his treatment and injecting morphia. It was also alleged that while putting the leg in plaster manual traction was used, using excessive force with the help of three men though such traction is never done under morphia alone, but under proper general anaesthesia. Dr Joshi in his reply denied the allegations by saying th. ' no general ahaesthesia was given considering the exhausted condition of patient. It was decided to immobilise the fractured femur by plaster of Paris bandage, and no excessive force was used. However, on evidence the court felt that Dr Joshi was negligent. It came to the conclusion that it was due to shock resulting from reduction of fracture attempted without taking the elementary precaution of giving anaesthetic to the patient.

Speaking about the duties of doctors the court repeated the British and American law saying, "The duties which a doctor owes to his patient are clear. A person who holds himself out ready to give medical advice and treatment impliedly undertakes that he is possessed of skill and knowledge for the purpose. Such a person when consulted by a patient owes him certain duties, viz, a duty of care in deciding whether to undertake the case, a duty of care in deciding what treatment to give or a duty of care in the administration of that treatment. A breach of any of these duties gives a right of action for negligence to the patient".

(3) The third case was decided by the Bombay High Court in 1975. This case reads like a doctor's apology. Philips India had appointed a doctor to give treatment to the employees. One employee contacted smallpox and died. The doctor had treated him for veneral disease. The court felt that there was a genuine error of judgment and since the particular variety of smallpox was fatal, the doctor anyway could not have done much. The problem with the case is not that it exonerated the doctor, especially considering the peculiar facts of the case, but the extent to which it sought to protect doctors. The court expressed the view that negligence for doctors should be interpreted much more narrowly than negligence of others, i e, the doctor has to be placed on a high pedestal and held to be negligent only if it is totally unavoidable.

Of course, this case is not likely to have any impact on subsequent cases, but still it shows the attitude of the judges. The important point decided by this case, however, was in holding that if the doctor had been proved to be negligent, the company which employed him would also automatically be negligent.

All the three cases relied only on English law books—by of course picking and choosing what suited the court's conveniance.

Politics of Torts

A proper understanding of the rise of 'negligence law' requires an analysis of the development and rise of the Tort Law. An extensive application of tort law is found only in developed capitalist countries. Developments at similar scale cannot be expected in third world countries. Let us therefore look at the causes which gave rise to tort law in developed capitalist countries.

In the earlier period, law was largely preoccupied with personal status, control over resources (primarily land) and the development of contractual relations (mercantile capitalism). Industrial capitalism transformed the entire social structure, engendering urbanisation which enormously increased the frequency of interaction among strangers. Important, because unlike aquaintances or intimates strangers would have less incentive to exercise care not to injure one another inadvertently and would find it more difficult to resolve the differences when injury occurred. At the same time interaction between friends and intimates became progressively limited—ultimately confined to the nuclear family. Intimates commit most intentional torts. But within the nuclear family they are rarely resolved by the legal system, (a) because they would destroy the relationship (b) the persons committing torts are sufficiently powerful.

Industrialisation gave capitalists the power to effect extensive damages first through domination of unprecedented

amount of physical force (factories, railways, etc) and now through toxic chemicals. Concentration of capital and mass production increased the number of workers, consumers and others who might be harmed by capitalists' indifference or miscalculation.

Capitalism also shapes the experience of injury. It must create a proletariat which must sell its labour for wages to live. It simultaneously destroys the obligation of mutual support outside the nuclear family and pays those within it who are gainfully employed at a level of wages too low to support non-production members. As inability to work becomes tantamount to destitution or dependence upon charity, the core of damages is compensation for loss of earning capacity.

Second, capitalists, middle classes and even industrial workers acquire consumer goods which require protection against inadevertent destruction.

Third, family is no longer able to care for injury or illness, partly as members must seek employment outside and partly because care itself is commodified and monopolised by the emergent medical profession. As the monopoly allows professionals to command high fees, injuries 'cost' a great deal more.

Finally, commodity form is progressively extended to non-productive experience.

Capitalist tort law exploits and alienates the victims in ways parallel to exploitation and alienation of labour. In pre-capitalist society, injury like work creates use value, it elicits cure from intimates who are motivated by concern and promotes demand for apology backed by threat of retribution. The capitalist state which asserts its monopoly of force to obstruct the latter response also creates a market for injuries in torts and legal system. It separates through the legal proffession tort victims from means of redressing their wrongs and medical profession disabled victims and intimates from caring for the ill. In each instance, a faction of the ruling class mobilises the power of the state in its own interests to protect the monopoly of expertise of lawyers and physicians. The lawyer then combines legal expertise with the victim's injury (as the capitalist combines capital with the workers' labour) to produce a tort (a commodity) that has exchange value both in the state-created market (the court) and in the dependent markets (negotiated settlements).

As capitalists have to maximise profit in a competitive market, they must sacrifice health and safety of others. Another reason why capitalism fosters injury is that it must expand its market and increase consumption; torts contribute to it just like planned obsolescence and warfare.

Tort law, following legal liberalism, eliminated formal legal discrimination. So, with its development discrimination between patients who are victims of charitable hospitals and those of non-charitable hospitals, etc, were eliminated. But it could not and cannot remove certain deeper inequalities.

First, of course, the inequality in the incidence of injury and illness: capitalists and professionals are subjected to totally different hazards than those suffered by workers at the work place or women at home. The rich can avail of the best medical facilities, equipment and medicines, not so the poor.

Secondly, the class and gender will affect the extent to which and the way in which the experience of injury is transformed into a claim for legal redress, the sense of entitlement to physical, mental and emotional well-being (women only recently began to legally resist abuse by their husbands, workers are only now coming to view hazards at work place as a negotiable demand), the feeling of competence to assess a claim, the capacity to mobilise legal process, ability to overcome delay, etc.

Third, the law also discriminates in the availability and generosity of the remedies it offers, the biggest difference being between tort damages and other compensation systems. An industrial worker is far more likely to be injured at work than a person from another occupational category: such injuries are relegated to workmen's compensation, which pays only a fraction of tort damages and rejects altogether certain tort categories. Other oppressed categories—women, children, dalits, religious minorities—are also excluded from tort recovery. They are most frequently the victims of violent crimes and other social crimes whose assailants are either unidentifiable, unavailable, financially irresponsible or simply too powerful. Women and children injured by relatives are left without any remedy.

Another type of discrimination is internal to the tort system. Pecuniary damages are paid on the basis of income of the person. Even the damages for pain and suffering are often expressed as multiples of pecuniary damages. So a poor person will get much less damages than a rich person. Women will get much less than men.

Production of Illness

Capitalist tort law systematically encourages unsafety. The dynamic of capitalism—the pursuit of profit impels the enterprise to endanger the workers, its employees and those who inhabit the environment it pollutes. As the cost of safety reduces profits a capitalist must be as unsafe as he can get away with being.

Apparently the Tort law curbs these destructive tendencies through the threats of damages. But this is not what actually happens.

First, compensation is paid on the basis of the status of the victim not of the offender—the doctor for instance.

Second, the insurance mechanism goes a long way in virtually nullifying the burden on the offender.

Third, as seen above, due to the discriminatory aspect of Tort law many injuries and victims are excluded from its purview.

In fact Tort law motivates the entreprenuers and the professionals to seek to evade the consequences of carelessness not to enhance safety. Their response to the threat to tort liability is to strive to externalise accident costs by concealing information. For instance, the market deterrence, by mandating the payment of money damages, subverts collective efforts to exert control over safety—damages are paid only for an injury caused by the offender's act. This means that unsafe conduct causing no injury is not deterred and that the legal attention is focussed on the temporarily delineated act of an individual rather than on the ongoing activity of a collectivity. Capitalist Tort law, like capitalist medicine, is obsessed with individual care at the expense of collective prevention because capitalism creates a market only for the former.

In fact the medical profession is not even interested in curing patients, only in 'treating' as many as possible. Also the costs of damages are externalised by increased professional

fees and insurance. In England, various Medical Defence Societies have been established. It there is a successful claim involving negligence of a hospital employee, the amount will be shared by the authority and society. As regards nurses, the Royal College of Nursing holds an insurance policy, idemnifying every member. So, ultimately the costs are passed on to citizens.

The Tort law is significant for the reproduction of bourgeois ideology. The fault concept upon which the law was built reinforces a central element of bourgeois ideology, individualism. Predicating liability upon the offender's fault and denying recovery because of the victim's fault perfectly express the bourgeois belief that each person controls his or her own fate.

Tort law offers symbolic support for inequality—by compensating owners for property damage it upholds the notion of private property and its concomitant, i e, the person's worth as a tort plaintiff is proportional to the value of the property he owns.

Also, by relegating injured employees to worker's compensation, which is limited to a fraction of the lost wages, the law treats workers like pure labour value, implicitly denying that they undergo the pain and suffering for which tort victims are given compensation.

Finally, Tort law assumes that for every pain suffered there is some equivalent pain which will erase it, a pleasure that can be bought with money and, therefore, the judges must simulate a market in sadomasochism by asking themselves what they would charge to undergo the victim's misfortune.

Also the Tort law treats all relationships as forms of prostitution—the semblance of love exchanged for money: Tort law thus generalises the feminist critique of marriage. Just as society pays 'pain and suffering' damages to the injured victim who is shunned (so s/he can purchase the commodified care and companionship that will no longer be volunteered out of love and obligation), so it pays damages to those who loved him, compensating them for their lost 'investment' in the relationship (so that they can invest in other human capital).

The Socialist Approach

The primary concern of a socialist alternative should be to ensure that those at risk regain control over the threat of injury and illness: compensation must be subordinated to safety, although the former goal remains important.

Even if all defects in the capitalist compensation system are removed—100 per cent damages, etc—two defects are irremediable.

First, it would mean spreading the costs across society through a social welfare scheme but does not mean spreading the risk of accidents more equally.

Secondly, valuation of injury and illness is still done by the state and not by people who suffer it. These are the problems in New Zealand where since 1974, in place of negligence they have what is called a 'no fault' compensation system.

A just system should be based on substantive equality. It should respond to all victims. Equality amongst victims would mean response to their needs whether or not their misfortunes were caused by fault or by human actions. The second is that the qualities of wealth and income should not be reproduced in the level of compensation.

It is obvious that tort law can develop extensively only in developed capitalist societies—only where there is a strong dominant ideology of bourgeois individualism, extensive and all-pervading commodity production (where everything is measured in term of money) and certain minimum standard of living where victims have the 'staying power' in courts, and offenders have sufficient means of payment. This, of course, is not the case with India, where we have a backward capitalist economy. Even then with the growth of capitalism more and more actions in torts are likely to arise.

Conclusion

Medical malpractice is already a well entrenched litigation sphere in western countries. Though in India uptil now there has been precious little happening on this front, it seems that more and more medical malpractice claims are being filed since the past five years, and over the next decade or so this branch will acquire at least some significance.

One cannot deny the fact that medical negligence claims are an offshoot of industrial capitalism and premises on the bourgeois ideology. Accountability of doctors coupled with redress for the victim can be much better tackled through and for a greater extent solved in societies not based on competition, treating injuries as commodities. The existing negligence law is not a panacea. But given the circumstances, it serves a useful purpose at least to an extent to mitigate the victims and bring accountability to doctors. In fact it should be seen not just as a reflection of bourgeois ideology but also as a bourgeois democratic right which requires to be extended and expanded. Also, in a country like India, where especially the poor receive extremely negligent medical treatment, extensive application of medical negligence law by people and by progressive groups can be very helpful to people and at least some way of improving health services. Also, surveys in US indicate that medical practice litigation provokes greater care at least in diagnosis.

One can only end by saying that despite its limitations, the law of medical negligence should be as widely used in India as possible.

Banning Pre-Natal Sex Determination-I

Issues and Debates

by teesta setalvad

Five years of extensive campaigning by women and health activists has resulted in a legislation banning the selective abortion of female fetuses through the misuse of amniocentesis and other technologies. What have been the major issues which have emerged in the course of the nation-wide debate?

FIVE YEARS of extensive compaigning by women and health activists have earned us the assurance of proposed legislation banning the selective abortion of female foetuses through the misuse of amniocentesis and other technologies.

The legislation will be restricted to Maharashtra despite the centre's assurances of a countrywide law. This limitation could prove fatal to the effective implementation of the aims. The lack of a ban in neighbouring states, where the practice of selective abortion of female foetuses has grown in alarming proportions since 1983, could prompt a largescale burgeoning of clinics offering this facility indiscriminately, just across the Maharashtra border.

Though the central government has given all possible indications of passing an all India law banning the selective use of amniocentesis and other technologies, and a special committee to recommend the terms of this legislation had been appointed in March 1987 which has submitted these to the government around September last year, New Delhi seems to have chickened out of the issue. Laudable though the decision of the Maharashtra government must seem, it must be remembered that in Gujarat, Punjab, Haryana, and even New Delhi, the country's capital with these clinics blatantly offer these facilities.

Debate among activists demanding such legislation centred around two points, whether such a ban should be total or selective and if the latter, which clinics should be exempted: in the interests of the benefits of some of these tests that are vital in detecting the genetic abnormalities of a foetus. Many activists, though genuinely fearing the growing trend of such selective abortions, expressed grave reservations that such legislation would only push these tests underground. Legislation cannot and should not be the aim of such a campaign. Such legislation that precedes the change in social mores and attitudes so drastically must be backed up by certain schemes that create conditions for the aims of the law to be implemented. The debate among activists on the question of a ban, selective or complete, focussed around two main issues: the overall status of women in the country that can lead to such largescale abortion of female foetuses and the grave question of the misuse of advanced technologies, ignoring its impact on the health of women. Several democratic and liberal forces ranged against the discussion and strove through their stand to defend that ultimate test of freedom—choice.

Are choices exercised in a vacuum? The scores of women interviewed and questioned by journalists and activists clearly enunciated the rationale behind their exertion of the supreme choice—to abort after the result of a sex determination test showed the foetus to be female—to save their skin from torture or battering, to maintain their status within the marital home, to save a marriage on the rocks. All this because of the *woman's* supposed inability to bear a son.

Even more infructuos arguments were used. These included the defence of amniocentesis and other tests as a tool to reach family planning targets. Another devious counter to the increasingly vociferous protests from women's groups was the postulate that the status of women would naturally improve in societies where the sex ratio has declined. Both arguments, it needs to be stressed, have been effectively countered.

Sex determination tests do not guarantee a male child. They merely ensure multiple abortions (that is an abortion for every second foetus tested for its sex) which can do immense, if not irreparable harm to a woman's health. Women are being increasingly used and singled out as target groups (and as a result, victims) for family planning and amniocentesis is part of this trend. Lack of food, clean drinking water and a total denial of economic securities and safe clinical facilities have led to a situation where one woman has to have 6.2 children to ensure one surviving male child. The argument therefore, that successive abortions followed by amniocentesis act as family planning tools is untenable.

Research studies on societies having adverse female sex ratios, reveals that customs like polyandry, sharing a wife (outside wedlock) abduction and purchase of women are widely prevalent in such societies. Besides, it is strongly felt that adverse sex ratios may in fact lead to an increase in incidence of rape, prostitution and grave controls over women.

Female mortality was 60 per cent higher than that of males in the age group upto five years. Today, in a situation where the sex ratio is declining, this 60 per cent higher mortality exists upto 8-9 years among girl children.

Faced with these social circumstances, and now assured of legislation completely banning the use of these tests for sex determination of the foetus, activists belonging to the Forum Against Sex Determination and Sex-Preselection (FASDSP), the umbrella organisation of several groups, have forwarded their demands to the government that would give more teeth to the proposed law. Greater powers, like the one to seize and examine documents must be given to voluntary organisations that make up the Vigilance Committees to ensure that the proposed law is effectively implemented. Moreover, the FASDSP is also demanding that these Vigilance Committees consist of adequate representation from voluntary organisations, doctors and government officials who have powers under the Criminal Procedure Code to ensure concrete results.

The Forum is also asking for the inclusion of all internationally accepted indications and 'exposure to potentially teratogenic chemicals and/or radiations' in the eligibility criteria for prenatal diagnosis. The creation of an all-India supervisory body, like a Technical Expert Committee to issue,

renew and cancel licenses and ensure uniform standards at the places approved for prenatal diagnosis, has also been demanded. Periodic inspection visits by this committee to those centres granted licenses to carry out these tests could act as a monitor.

Since the entire campaign, spanning over five years had exposed the blatant ambivalence of the medical profession on an essential question of medical ethics. the FASDSP is also asking for suitable amendments to the Indian Medical Council Act to enable cancellation of the registration of those doctors found violating this proposed legislation. The Forum argues that the two processes of collection of samples and the testing should be de-linked. The former, that involves a collection of the amniotic fluid in safe and hygenic conditions could be carried out at the medical college level after careful screening of applications. Thereafter the testing must be carried out at genetic counselling laboratories where the testing, with sophisticated machinery need be done. Misuse of ultrasonography for sex determination should also be an offence though ultrasonography itself must be excluded from the purview of the ban due to its varied application. The government is considering imprisonment and fine to the offenders and the Forum is stressing that women who undergo these tests must not be punished.

It can be clearly seen that the emphasis, at every stage, in the recommendations put by the FASDSP, for the legislation to have any use, is on vigilance. Vigilance that involves a high level of commitment from both volunteers and officials who participate in the process. The limitations of just resting with this legislation cannot be underemphasised. The greatest problem being the blind preference for a male child, in a patriarchial society where male attitudes and values dominate.

Maharashtra and Gujarat, have over the last few years implemented schemes aimed directly at promoting the girl child/children family norm. Felicitation from the state to a family with only girl children, a special green card that procures extra rations, concessions in education apart from an all out publicity campaign have already begun. Moreover, one of the promotion schemes started in Maharashtra depcit not merely the single girl child family but portray the woman at the helm, making all relevant decisions concerning health and family. Apart from enthusisastic vigilance from voluntary agencies, commitments of this kind in the state's health policy could make the social impact of this legislation more effective. The aim is to give the woman, from girlhood her rightful place and share in society.

Pathetic Attitude of Doctors

More than anything else, the public debate that preceded the legislation reflected as never before the pathetic 'neutrality' of the medical profession on the ethics of the issue. Whereas more 'glamorous' questions like euthanasia draw the most eminent into the pros and cons of the debate, the selective abortion of female foetuses left the top medicos unmoved.

On the contrary, until pushed into a corner on the blatantly embarassing statistics provided through studies conducted by several organisations, medical practioners openly said that 'amniocentesis and appendicitis were their bread and butter.' At as much as Rs. 500 per sample taken, even in remote rural areas, amniocentesis for sex determination has become a lucrative commercial proposition. The number of such centres, with not even minimum standards has proliferated. In Bombay, the capital of Maharashtra the number has gone up from three to at least 20 in the period between 1983 and 1986. The larger of these sex determination clinics perform a minimum of 1,500 amniocentesis tests a year.

The Voluntary Health Association of India (VHAI) has pointed out through a study that the chances of a premature delivery in a woman having undergone amniocentesis are as high as four per cent, and the risk of abortion as high as 1.5 per cent. With these tests normally being conducted in the fourteenth and fifteenth weeks of pregnancy, abortions that follow in the second trimester are inherently dangerous. It need not be mentioned that these risks were either not revealed at all by the doctors performing these tests or, were grossly underplayed. Unless the culpability of the medical profession is assured through the proposed legislation, loopholes that already exist through provisions of the Medical Termination of Pregnancy (MTP) Act that enable a woman to have an abortion, could be exploited while this abhorrent practice continues unabated.

If effective vigilance is not maintained and these tests continue to be available at different centres for sex determination underground, there is no way in which the offence could be detected at the stage at which a woman comes for the medical termination of her pregnancy, that is, abortion. Under the MTP Act, a section provides that a woman can undergo an abortion for 'failure of contraception'. It is being argued that this section could be misused by unscrupulous medical practitioners in league with family members of the woman who have managed a test that reveals the sex of the foetus.

Apart from this, another lacunae exists that can be blatantly used by practitioners to escape the law. This was brought out through a case filed by the Mahila Dakhsata Samiti in the Bombay High Court after 21-year old Sunita Chaturvedi, mother of two girls, died as a result of an abortion that followed a sex determination test. The case which came up before the High Court in October 1986 but has lain in cold storage since, cited the victim's husband, Girdhari Chaturvedi and two doctors Dr. Meenaxi Merchant and Dr. Rajani Arya as respondents. Apart from making out a strong case against the misuse of amniocentesis, this pattern that has failed to move legal brains, reveals how section 8 of the MTP Act can be misused by unscrupulous doctors to shield themselves from the consequences of heinous acts.

This section, provides that no suit or other legal proceedings can lie against registered medical practitoners for any damage caused by any action committed 'in good faith.' Abortion followed by amniocentesis, dangerous and fatal though it might be in the second trimester of pregnancy for the woman, can leave a doctor untouched if this section remains. Such lacunae in the law can be misused against whatever limited benefits that the proposed legislation selectively banning these tests might achieve. Social attitude apart, it must be remembered, medical practitioners though now somewhat hedged in with the threat of legislation, are likely to be the main contenders of the law.

Unless an internal code of medical ethics or specific provision in general criminal law hold them accountable, the

Banning Pre-Natal Sex Determination-II

Scope and Limits of Maharashtra Legislation

amar jesani

The Maharashtra government's bill regulating the use of prenatal diagnostic techniques is a concession to the demands of the five-year long campaign. It is also an indictment of the Medical Council for its open disregard of its own code of professional ethics. On the other hand, it carefully avoids touching the private sector, makes a mockery of people's participation and offers many concessions to the medical lobby.

THE Government of Maharashtra has recently introduced a much awaited and talked about bill in the state assembly, "Maharashtra Regulation of Use of Prenatal Diagnostic Techniques Act, 1988". The bill has come in response to a concerted campaign mounted mainly by the Bombay based Forum Against Sex-determination and Sex-preselection and supported by organisations of women, doctors, health activists, democratic rights activists and even a research institution. These groups organised demonstrations, marches, *dharanas*, exhibitions, seminars and workshops. They also used all available media to draw people's attention to the rampant misuse of medical techniques like amniocentesis, chorion villi biopsy, sonography leading to female foeticide. Many sensitive journalists and other media people helped focus the campaign not only on the issue of misuse of medical techniques but also on the status of women in our society. Several members of these organisations also accepted the government's invitation to participate in a committee which did some necessary groundwork to identify the technical and legal issues involved in stopping this misuse. The bill presented in the Assembly was, however, drafted by the government on its own.

Medical Council Indicted

Although the statement of 'Objects and Reasons' given by the minister of state in the bill, does not explicitly criticise the Medical Council, states that "In breach of professional ethics, unscrupulous medical practitioners do not hesitate to perform abortions even when the sole or one of the reasons for doing so is female foeticide". It also laments that "there seems to be a misconception about the objectives of the existing laws in the minds of many medical practitioners". It seems naive to enact a full-fledged legislation if the issue involved was only a simple misconcept about the existing laws. But to expect the government to be forthright in its assessment of the medical profession is asking for the moon.

Nevertheless, this statement brings out that sex-determination practices involved in breach of medical ethics. Therefore, it squarely indicts the Medical Council. The MC in our country has scarely made any attempt to regulate the medical profession according to the code of medical ethics formulated by it. It has not only allowed the violation of ethics to go unpunished but also at times attempted to provide justificaion and legal cover to such violation. This attitude was very glaring in the specific case of sex determination where it refused to shed its lethargy despite a very hot debate in the media for last seven years. Not only that, in a private conversation, the president of Maharashtra MC defended sex-determination practices of the doctors saying that the medical profession must grant full autonomy to the patients. It was also argued that it is difficult to prove in individual cases that sex-determination was done to get female foetuses aborted.

There are enough provisions in the code of medical ethics of the MC to take stringent action against the profession on this issue. Some individual cases also came to notice but the MC did not move. For instance, Dr. Datta Pai, who runs an abortion clinic (Pearl Centre) in Dadar, Bombay and who was a member of the government's committee on this issue, has publicly admitted that his abortion centre had provided facilities for amniocentesis till he was invited to join the government committee, though he never admitted that amniocentesis was used for female foeticide in his centre. Yet this was a fit case for the MC to seize his records of amniocentesis and the MTPs in this period and scrutinise whether in the same centre women who underwent amniocentesis were offered MTP when the foetus was found to be female. And if it were found to be so, the MC could have used two clauses of its code, namely, first, no discrimination in medical practice and second, the social responsibility of doctors, in addition to the violation of the MTP act, to punish the guilty persons.

Thus, though this bill is a concession to the Forum's demand, it is also an indictment of the Medical Council for its open disregard of its own code of professional ethics.

In our country only drugs and pharmaceuticals are regulated under a full-fledged law (albeit, a very ineffective law). The rest of what constitutes medical technology and techniques are not regulated under any comprehensive law. This bill restricts itself to the regulation of pre-natal technologies and techniques. Again, it does not regulate the introduction of new technologies and techniques even in pre-natal diagnosis. In fact it regulates only their use. Nevertheless, it is an admission of the fact that medical technologies are being misused in pre-natal diagnosis to such an extent that an independent law is needed to deal with them. By logical extension, it could be said that it gives room for health activists to push the idea that all medical technologies and techniques could be widely misused, and they are being misused, therefore stringent regulation on all medical technologies in general and new technologies in particular is urgently needed.

Secondly, it explicitly bans the use of medical techniques and technologies for the purpose of pre-natal sex determination leading to female foeticide. Thirdly, it declares illegal the giving of any advertisement in any manner regarding

facilities available for the pre-natal prediction of sex at the centre, laboratory or clinic. Thirdly, it makes illegal the seeking of such facility by the woman or by any other person for her for the pre-natal determination of sex. Fourthly, it prohibits the indication of "the sex of a foetus with or without the possible object of female foeticide". And lastly, it prescribes rigorous punishment to those who indulge in pre-natal sex determination activities.

Thus, the pressure generated by the Forum's and other individuals and organisations' efforts has helped make some breakthroughs in the present situation. But the gains are quite inadequate in many respect and this bill is a big compromise solution worked out by the government and the medical authorities—both private and public. These inadequacies make the bill, if not weaker, than at least as weak as the present Drugs and Cosmetics Act. In many ways it is a defeat in the victory for the Forum.

Sacrosanct Private Sector

The Forum has, from the very beginning, demanded the abolition of pre-natal sex determination techniques in the private medical sector. For it is the private medical sector which is primarily guilty of their misuse and not the public sector. In government institutions the government has issued a directive almost a decade back to stop their usage for sex determination.

However, the government with talks of inefficiency and corruption in the public sector is building a case for privatisation (which is already underway). It has failed to even pay lip-service to the nationalisation of the private medical sector despite such revelation of gross malpractices. It even fails to acknowledge that the 'liberalisation' that is prevailing in the private medical sector, has brought only ills for the people and for the women in particular.

Instead of abolishing all genetic laboratories and genetic clinics in the private sector the bill only wants to regulate them. As we know that such a regulation of the pharmaceutical industry under the Drugs and Cosmetics Act has not radically changed the drug scene and its misuse continues in *legal* as well as illegal manner. The regulation of genetic laboratories, genetic centres, genetic clinics, gynaecologists, medical geneticists and so on will ultimately entail the creation of an administrative set-up which will look like a mini-FDA. The expenditure that government will incur and what people will pay for these services in these centres, in the name of registration fees will far off-set in a few years the total expenditure the government would have made as a compensation in taking over all genetic laboratories in the state. As a bonus, this would have made the implementation of the ban easier and effective without depriving those women who medically need pre-natal diagnosis.

The story of regulation does not end here. The body (called Appropriate Authority (AA) in the bill) which will grant licenses and enforce the law is full of those health bureaucrats who are already overloaded and proven to be inefficient in regulating their own departments. The Director and the Joint Director of Health Services, who will become ex-office chairman and secretary of the Appropriate Authority respectively, have never made any serious attempt to curb private practice by the doctors in our rural health services. Further they are in charge of an ever-expanding rural health infrastructure which includes over 1500 primary health centres and about 200 rural hospitals. In addition they also manage cottage hospitals, district hospitals etc. They are hardly able to efficiently regulate these establishments. One can only imagine with what efficiency they will be able to regulate private medical profession and its ever increasing number of laboratories.

The composition of the Appropriate Authority (AA) is: Two ex-officio government bureaucrats from the public health department, one bureaucrat from the medical education department, one bureaucrat from the Indian Council of Medical Research, two doctors: one gynaecologist and one geneticist (no other qualification mentioned) and two representatives of voluntary organisations (in the field of health, women and human rights). Except ex-officio members, the rest in the eight member team will be nominated by the government. Thus, the participation of voluntary organisation will be as per the needs of the governments and since the AA will take decisions on simple majority, the voluntary organisations will not have much decisive say in most matters.

Mockery of People's Participation

This bill is a classical example of what the government means by people's participation. As stated above, the selection of the voluntary agency to be represented in the AA will be made by the government and not the people. Further, there will be another agency called the state Vigilance Committee (SVC) to oversee the implementation of the act. Here also, in the seven member committee, two representatives of voluntary organisations will be appointed by the government. In its supervisory functions, the SVC will pay periodic visits to the recognised centres, but it will not have authority to take action against those violating the act. For this the SVC will have to approach the AA.

Further, on the one hand representation to the voluntary agencies in the implementing bodies is given under the guise of people's participation on the other common citizens are forbidden to directly prosecute erring doctors, centres and laboratories. Such citizens will have to first approach the SVC and the AA with their complaints. There is, however, a provision for such citizens to go to court after giving two months' notice to the AA about their complaint. But to counterweigh such action, the AA and SVC, which will be in possession of all information needed to prosecute doctors, centres and laboratories, are given the power to refuse to make information available to such citizens if the same is, in its opinion, against the public interest. Thus, in the last analysis, while talking aloud about people's participation and extending an olive branch to the voluntary organisations, the government has made clever provisions in the bill to see that even those people who want to participate to stop the misuse of pre-natal diagnostic techniques cannot do so or are effectively frustrated in their efforts.

Concessions to Medical Lobby

The pressure exerted by the medical lobby while the bill was being drafted is clearly visible at several places. This is not surprising. The medical bureaucracy has time and again, on various issues (recently on the issue of charging for services) expressed its sympathy for the values of the private

sector. Further, people like the president of Maharashtra MC and Dr. Datta Pai are close advisers of the government health department.

In the defining indications and conditions for which pre-natal diagnostic techniques should be used, they have seen to it that the Forum's proposal of getting written opinion of three concerned specialists has been completely excluded in the bill. In the absence of such a provision, the private gynaecologist will be the sole decision-maker whether to offer pre-natal diagnostic facility to the woman or not. However, vague indication like the history of two or more abortions or foetal loss could be misused in the same way as the failure of contraception as an indication is used for the MTP. Just as the failure of contraception as indication for the MTP has *rightly* made abortion facilities legally available to women, the indications like foetal loss will *wrongly* make available sex-test to women who want to go for female foeticide.

The medical lobby has scored the most in the chapter on 'Offences and Penalties'. This chapter identifies three types of offenders. Type one: Doctors, centres and laboratories. Type two: The woman who seeks the test, her husband and in-laws. Type three: All those who contravene any of the provisions of the act.

The penalty prescribed for type one offenders is rigorous punishment upto three years and fine upto Rs 5000. To demonstrate that the government is going to be very strict with offending doctors, centres and laboratories, the bill has a clause here saying that the minimum penalty to these people should be at least one year imprisonment and fine of Rs.1000. But the hollowness of this provision becomes evident as we read the last clause of this chapter. This clause empowers the court, if it so desires and after giving reasons, to award less punishment than the minimum stipulated under the act. That is, a rich doctor who has misused the techniques leading to female foeticide, can, with the help of powerful lawyers, persuade the court to award minor punishment.

The second type of offenders include the woman, her husband and her in-laws. The bill says that the woman should be assumed to be innocent and thus charged only Rs 50 as a token fine and no imprisonment. The bill also says that it should be assumed that she was compelled by the husband or in-laws to undergo the sex-test. The husband or her in-laws will be punished for abettment of the offence, with rigorous imprisonment upto three years and with fine upto Rs.3000. The bill says, "The court shall always assume, unless otherwise proved, that a woman who seeks such aid of pre-natal diagnostic procedures on herself has been compelled to do so by her husband or members of his family". Here the catch is provided with the addition of words "unless otherwise proved". It is easy to prove that the victim woman will be caught and not the husband or in-laws. Who will prove it otherwise? If the husband is arrested, he will simply say that he did not force his wife to undergo the test. Now, in our society, what is the wife going to say? Of course, she herself will come forward to prove that she was not under compulsion. Feminists and their supporters were fighting against the government to save the woman who is a victim of the patriarchal system. This bill makes the victim a criminal who will have to serve upto three years in prison. This is an outright anti-woman provision. The earlier everybody starts raising their voice against it the better.

We all know that there is inequality in our society. But our constitution says that everybody is equal before the law. We all call it formal equality. But not so in this bill. There is no equality between the doctors, centres and laboratories on one hand, and the victim woman and her husband or in-law on the other hand. The bill says that the offence committed by type two and type three offenders "shall be cognisable, non-bailable and non-compoundable". This means, when a complaint is made to the police against the victim woman, her husband or her in-laws, the police has to act to arrest them. Once arrested, only the court can give bail. The non-compoundablity makes it difficult to get any compromise settlement.

But the type one offenders (doctors, centres and laboratories) are excluded from the above provisions by making their offences, non-cognisable (the police is not required to act when the complaint is filed), bailable (if arrested at all, can get out immediately on personal bond, i.e., the police itself can grant bail) and compoundable (can hammer out an out-of-court settlement).

This shows that our government considers the offences committed by the doctors less criminal than those committed by the victims (who paid that doctor exhorbitant amounts). In our society the person who actually commits female foeticide by doing a sex-test and selective abortion is less of a criminal than victims of patriarchal ideology and physical and socio-economic compulsions.

Some Lessons and Future Plan

This bill has once again emphasised that only good intentions of some individuals, groups and the 'goodness' of some bureaucrats do not add upto desired change. This is not to question intentions, but the methodology of affecting change and the ultimate gains. The system does not like to have gross irregularities in its functioning. The current system permits irregularities outside its rules only upto the time it needs them. Thus, the government will also be found responding to certain demands for establishing the rules of game in the fields where such irregularities are rampant. Only such an approach can keep up the credible face of the system before the masses.

But these rules of game, under the pressure of small groups and media, are not framed while punishing the guilty. The Environment Act came without punishing Union Carbide. The industry was not punished before bringing the Consumer Protection Act. In the same way the builders are not going to be disciplined before the housing act is brought in. And no doctor is so far penalised for committing female foeticide. This shows the light-mindedness of the government and the feebleness of the efforts made by the groups concerned. As a result, all laws are passed but they are toothless laws.

Therefore, the groups who campaigned against female foeticide cannot remain complacent. They must continue their campaign raising their original demands like abolishing pre-natal diagnosis in the private sector, absolute protection to the victim woman and so on. They must, while going to the masses with those demands, also demand amendments in the bill. If the bill is made a law without demanded changes, the campaign must be continued. At the same time,

(Contd on page 98)

Good Manufacturing Practices

How Serious is the Government

amitava guha

Through a notification the government has introduced a draft amendment to the Drugs and Cosmetics Rules, 1945 which are aimed at introducing Good Manufacturing Practices (GMP) in the pharmaceutical industry. But clearly, the government is not at all serious about implementing these measures as becomes obvious if the draft GMP is scrutinised.

THE DRUGS and Cosmetics Act, 1942 and Drugs and Cosmetics Rules, 1945 are both ancient laws. They have to render minimum check and control on production, distribution and marketing of modern pharmaceuticals. It is also proved that this Act and its rules although amended in 1979, 1980 and 1982, cannot provide the government adequate power even to ban a harmful drug. The Government of India, through a notification of June 22, 1987 had introduced a draft amendment to Drugs and Cosmetics Rules, 1945. The amendments are aimed at introducing Good Manufacturing Practices (GMP) and it is stated in the notification that:

> Any objection or suggestions which may be received from any person with respect to the said draft rules before the expiry of the period (thirty days from the date on which the copies of the official gazette in which this notification is published are made available to the public) so specified will be taken into consideration by the Central government.

What is GMP

In USA in the early 70s a large pharmaceutical company was convicted when due to faulty manufacturing practices, a drug manufactured by them caused a large number of deaths. The same company, aiming to refurbish its image and goodwill proposed to other manufacturers a self regulatory code for manufacturing of pharmaceuticals. Later, the World Health Organisation took the initiative to prepare a norm of Good Manufacturing Practice. At the 28th World Health Assembly in 1975 the revised text of 'Good Practices in the Manufacture and Quality Control of Drugs' was adopted. It was recommended that all member states (which includes India) should apply the requirements of good manufacturing practice.

The practices laid down in GMP are designed to ensure that the drugs received by the consumers have been subject to stringent control from the beginning to the end of the manufacturing cycle to ensure that they are of high quality. The expression 'manufacturing' for this purpose refers to all operations involved in the production of a drug including processing, compounding, formulating, filling, packaging and labelling.

WHO has grouped GMP in mainly the following sections—personnel, premises, equipment, sanitation, starting materials, manufacturing operations, labelling and packaging, quality control system, self inspection, distribution records, complaints and report of adverse reaction. It has provided very broad guidelines of GMP for its adoption in a suitable form by the member countries. It took India about a decade to think of implementing the decision of the World Health Assembly on GMP.

Without a high standard of ethics it is impossible to maintain GMP. In developed countries drug manufacturers had, on several occasions, faced strong criticisms, litigations resulting in heavy compensation and stringent government regulations. The GMP is self-regulatory and not a compulsion under law in the developed countries. It was found that the same international company which maintains GMP at their establishments in parent countries, does not care to do so at their establishments in the underdeveloped third world countries. In some countries statutory actions have to some extent forced the multinationals to follow some kind of ethics. The Indian experience is different. The Committee on Drugs and Pharmaceuticals (Hathi) expressed its concern on the rampant violation of laws by the drug multinationals in India. Despite this, the Government of India had decided to enforce GMP only by changing the statute. It is, therefore, necessary to analyse the nature of the amendment the government intends to introduce and the consequences of the statute if it is truly implemented.

Some Problems Relating to GMP

WHO had suggested Good Manufacturing Practice for the manufacture of formulations only. There is as yet no code/guideline for manufacturing basic bulk drugs. This is particularly disturbing when now-a-days multipurpose pharma plants are capable of producing more than one drug in the same process plants.

A company may produce a combination of two or more drugs of high technical quality and bioavailability but the combination itself may be irrational and not needed by the population of the country where it is marketed. GMP should also cover these drugs. WHO had defined GMP as 'pre-marketing quality assessment' the essential factors of which are:

"A notification procedure: is the the least resource-intensive ways of obtaining information on drugs offered sale in a country. The amount of information required for notification may vary. It may be initially restricted to the name of the drug and manufacturer, and may then be expanded to include the nonproprietary names for active substances, the composition, including inactive ingredients, and pharmacological classification". This will eliminate all irrational formulations which have no place in any standard books of pharmacology.

"An authorisation procedure: can be developed in which either all drugs or specified ones only require an authorisation before they are marketed in the country. This may vary

in its stringency but it almost always incorporates the element of inspection of the manufacturer and the verification of product quality by analysis.

"A registration procedure: comprises the evaluation of data intended to prove the safety and efficacy of the drug and to determine the indication for its use. The registration may include an assessment both of the drug and of the manufacturing procedures".

Pre-marketing quality assessment therefore should form an integral part of GMP. This is missing from GMPs adopted in most of the countries.

The other thing which is missing in these GMPs adopted in the other countries is a complete set of guidelines for post manufacturing surveillance which should include the marketing code also. This we need to discuss more in the context to our country.

It took a decade for the Government of India to formulate GMP after they participated in 28th World Health Assembly where the resolution on GMP adopted. It is clear why the government suddenly became so conscious of the need to introduce an amendment and pass it in a short 30 days' time. This of course, follow the recent pattern of the government taking snap executive decisions bypassing even the Parliament. Causal, non specific and absurd rules have been suggested that too without determining any logistics for their implementation.

We have three major laws and regulations which govern production and sale of drugs: Drugs and Cosmetics Act 1942; Drugs and Cosmetics Rules 1945; Magic Remedies Act. In UK the main law is the Medicines Act, 1971. There were 34 regulations set out by British government (upto 1981) to govern the production and sale of drugs many of which are directly and indirectly connected to GMP.

There are major inadequacies in the government's draft GMP as far as the premises and equipment are concerned. In the draft only eight points are mentioned while in British GMP there are twenty-two specific directives. The draft says: "They (the building) should conform to the conditions laid down in the Factories Act, 1948 (63 of 1948)'. It is well known that because the age-old Factories Act has been of no use in regulating the conditions of the technologically developed modern factories the government has brought forth a further amendment to the Factories Act. What type of control then can one except from this Act on the 'high tech' pharmaceutical factories?

The draft also had not cared to look into the effect of factories on environment inside and outside the premises. There are international standards on the limit of toxic materials and suspended particles in the air. The draft GMP has totally ignored it. Not only this, the draft has not dealt with the disposal of containers of bulk drugs and other materials which may not loose potency by simple washing with soap water. Nor does it mentioned how and where to dispose toxic effluents. The British GMP, in contrast to our draft, says:

> Waste materials should not be allowed to accumulate. It should be collected in suitable receptacles for removal to collection points outside the buildings, and disposed of at regular and frequent intervals. Special care is necessary over the disposal of waste containing dangerous, highly toxic or sensitising materials (eg hormones, cyto toxic agents, sensitising antibiotics). Disposal of raw materials, printed packing materials and rejected products should be carefully controlled and documented.

The draft is extremely casual in this area. It is very vague and non specific when they state that the manufacturing area for sterile drugs "shall be provided with air locks for entry and shall be essentially dust free and ventilated with an air supply through bacteria retaining filters (HEPA filters)". While British GMP has a separate chapter containing 126 sub clauses for 'Manufacture and control of Sterile Medicinal Products', our legislators had to be satisfied with only two tiny paragraphs.

Various HEPA filters are used to create sterile conditions of air for different purposes. Therefore, a standard is needed to be fixed for production area of sterile materials. Not only this, there should be standardisation of specific final filter efficacy with recommended minimum air changes per hours and the equivalent classification of HEPA filters available in India. Absence of such standardisation will lead to the controversies in application of strictures and the manufacturers will take recourse to some other laws to evade this vague stipulation.

Another classic example of casual approach can be found in the draft under the peculiar heading 'All Medical Services' that "Medical inspection of workers at the time of employment and periodic check up thereafter once in a year, with particular attention being devoted to freedom from infection conditions and records thereof shall be maintained".

It is beyond the scope of anyone's understanding as to how check up once in a year will ensure that the workers had no infection in the remaining days of the year. We are yet to imagine a worker who is suffering from infective cold voluntarily informing the management of his ailment. When there are a large number of contract labourers working in both big and small companies reporting of such minor but contaminous disease may mean loss of wages for the entire week. British GMP is somewhat more specific in this respect: "There should be preemployment medical checks, and steps should be taken to see that no person with a disease in a communicable form, or with open lesions on the exposed surface of the body, is engaged in the manufacture of medicinal products."

The staff should be required to report infections and skin lesions and a defined procedure followed when they are reported. Supervisory staff should look for the signs and symptoms of these conditions".

In the industrial policy declaration of 1984-85, the government announced broad banding in the pharmaceutical industry. Astoundingly the government under the scheme mentioned that equipment each as mass mixers, cone blenders, drying ovens can be used under broad banding. The British GMP has elaborately dealt with how to avoid cross contamination and mix-up. The draft Indian GMP has only mentioned the term mix-up in a subheading but nothing has been specified as to how to prevent it. Nothing has also been specified regarding the use of masks, gloves, etc, in different manufacturing area.

There should be certain codes for pharmaceutical machinery manufacturers also. For example in most of the hot air driers the lining used is asbestos. The inner walls of such driers, particularly for drying pastes, are usually coated with heat resistant paints. There is every possible chances that such paints may be dislodged from the inner surface and get mixed up with the paste or powders kept in the trays.

It is also necessary that the GMP defines clearly the maximum permissible operations per punches of the tablet compressors after which they should be discarded. Similarly it specifies limits per use of filter bags of the fluidised bed driers, etc.

Experts who had drafted the GMP are so confident of their work that they feel that their work will remain unaltered for eternity. The draft has not suggested a periodical review of the conditions recommended. The first edition of 'Guide to Good Pharmaceutical Manufacturing Practices' was published in UK in 1971. Thereafter it was amended in 1977, and in 1985. It clearly states—"Time has shown that it would be helpful to rearrange and in places, clarify and enlarge the text and to give on further topics." Due to advancement in technology and scientific concepts GMP cannot remain static. In future GMP will need to include norms for electronic data processing and retrival systems.

Quality Control Laboratory

The section on laboratory practice is the most important and sensitive part of GMP. In fact a separate set of law/guideline is needed for this. In the 28th World Health Assembly it was decided that a comprehensive review of approaches to quality assurance system would be made (WHA 28.66). A document accordingly was prepared by the Experts Committee and its report was published in the twenty-seventh report of the committee. Thereafter, the committee has produced three more reports elaborating the quality assurance systems. The thirtieth report had reviewed and added more recommendations to the earlier reports. The draft Indian GMP has ignored these facts. In the 28th World Health Assembly a small guideline was prepared on quality control system giving some objectives. The draft GMP has simply reproduced these guidelines but has not elaborated on either the methodology or the stipulations which are needed for good laboratory practice.

A major decision which is needed to be taken is whether there should be any commercial establishments for certifying quality assurance. After the facts revealed in Justice Lentin's Commission chart how political power and profit dictates the reports of the private laboratories, it is high time we decided whether any private commercial laboratories be allowed to test drugs. On the other hand the government has only five test laboratories in the country to cater to 9000 drug firms registered under DGTD.

Further the government has not considered the prevailing set up in India while preparing a new edition of the Indian Pharmacopea which is a 90 per cent replica of the British Pharmacopea. Any unit, big or small wanting to establish its own quality control laboratory will definitely need microbiology testing system spectrophotometry system for both ultraviolet and visual range, etc. While the former needs a large of space and special furniture the latter costs a large amount of money. The minimum necessary equipment for such a laboratory needs an investment of Rs 3 lakh. The definition of a small scale industry till date is a company having turn over of Rs 50 lakh. How can such a company invest Rs 3 lakh for a quality control laboratory?

Moreover, considering that all companies would have their own quality control system where maintainence of a spectrophotometer would be a must would our government laboratories be in a position to supply International Chemical Reference Substances of all drugs (both active and inactive substances) for regular calibration of their instruments. Our experience is that even the government laboratories do not maintain all reference substances to calibrate their own spectrophotometers. The draft amendment only says: "Every manufacturing establishments shall have a quality control department supervised by approved expert staff. . ." It does not say anywhere what should be the minimum equipment to be maintained in this section.

It is also necessary to clearly describe the premises of the quality control laboratory—how they should be arranged; what are the hygenie conditions, temperature, humidity, sterility conditions etc to be maintained inside. How the instruments are to be calibrated and how often their sensitivity be checked under what standard. Similarly, the reagents need to confirm to a standard guideline. Guidelines for maintaining concentration, standardisation factors, shelf life and storage factors, should also be specified and how often the prepared reagents should be checked to find out their suitability, etc.

There should be clear guidelines as to the stage of collection of samples for quality testing and for identifying, preserving and recording the samples before and after testing. Documentation of the analysis is also of great importance as well as a good documentation system.

The draft GMP had not considered many other substances which are used for curative purposes. No GMP had been suggested for the manufacture of medical gases, or of radio pharmaceuticals. A large number of verterinary medicines are also used in ur country. The draft GMP says nothing about these not even that the GMP for other pharmaceuticals should be followed in producing veterinary medicines as well. Interestingly the British GMP says: "Some veterinary products such as those used for mass external treatment of animals (e g, sheep dips), have no direct equivalent among products for human use and the recommendations on manufacturing premises and equipment given elsewhere in the guide may not be appropriate."

Post manufacturing GMP

Two most important points not given any consideration at all by the draft GMP are post marketing surveillance and distribution. The responsibility of a drug company does not end with the manufacturing of a drug. The manufacturer needs to take care that the drug is stored under prescribed appropriate storing conditions in the factory warehouse and the same has to be followed by the middle men engaged in wholesale and by the retailers in the chemist shop also. Clear guidelines are needed to be specified for transport conditions particularly for a vast country like India. Where products in transit may be subject to conditions such as unacceptable degrees of heat, cold, light, moisture or other adverse influence including attack by micro-organisms and pests.

There should be certain specified norms regarding maintenance of stocks which are rejected due to damages for spillage or breakage. These are to be kept separated from the stocks of expired drugs. Proper recording, labelling and disposal is also to be specified. Therefore GMP should include 'Good pharmaceutical storage, distribution and/or wholesale practice' also.

There is virtually no system in our country to supply package inserts along with each sales pack of drugs giving important side effects, precautions, adverse reactions, interaction with other drugs, etc. Lack of proper norms of labelling has led to situations where sometimes it is very difficult to decipher the constituents of the active ingredients of the drugs from the labels. Brand names are printed in bold while the generics are printed in or in very small type.

In 1968, the 21st World Health Assembly adopted a resolution (WHA 21.41) urging member countries to enforce control on advertisements. The resolution stated the ethical and scientific criteria for pharmaceutical advertising and covered advertising to the medical and related profession as well as to the public. From the perspective of consumer protection, it is important that the consumer should be alerted to all side effects, contraindications, warnings, hazards, and precautions. It has been observed that a fair balance can be considered to be lacking if:

a) Information is included in an advertisement that has not been approved for inclusion in the promotional material at the time of registration.
b) Advantages are claimed for the drug without simultaneous disclosure of disadvantage.
c) Obsolete information is used
d) Claims are exaggerated
e) Animal or laboratory data are cited as clinical experience.
f) A statement by a recognised authority is quoted without also citing any unfavourable opinions of that authority.
g) Statements are used out of context.
h) Statistics are used in a misleading way
i) A headline or pictorial presentation is misleading (*Guidelines for the Development of a National Drug Control Programme*; Pan American Health Organisation; pp 79-80)

The draft GMP shall include all these conditions for the dissemination of correct and unbiased information.

Monitoring of a drug, new or old is continuous work. It has international impact also. Since 1960, the World Health Organisation had been insisting that all member countries should develop centres for monitoring adverse drug reactions. In the 1963 World Health Assembly it was resolved that the member countries would co-operate with each other in the dissemination of adverse drug reaction so that the best possible protection can be offerred to consumers.

In our country, no system of monitoring adverse drug reactions had been set up. Although a few such centres are in existence but they are often found to defend the hazardous drugs instead of monitoring their adverse reaction. A centre under the University College of Medicine, Calcutta was found, a few years ago, to be conducting a study financed by an industry house on the need of a combination drug—chloramphenicol and streptomycin. The head of the centre later published their study in support of this irrational and hazardous combination in the *Journal of Indian Medical Association.*

The draft GMP, under the subhead 'Records of Complaints and Adverse Reaction' only says that—"Reports of serious adverse reactions resulting from the use of drug along with comments shall be informed to the concerned licensing authority". This is the only thinking expressed in the draft regarding adverse drug reaction. The total responsibility has been left to the manufacturers who have no mechanism to keep track of adverse drug reactions. Their tendency is to suppress such information however rare it may be. Even accepting the fact that a manufacturer may report some incidents of adverse drug reaction, what would the government do? The draft GMP suggests nothing. In the event of such incidents, the British GMP elaborates on how to recall the product. The system of recall inflicts a red alert. It not only stop the sale of the product but also directs stoppage of the production operation till the reasons for adverse reaction are explored after investigation by the government authorities.

From the above, it can be concluded that while preparing the draft GMP, the government had not been in the least serious. Incomplete measures, casualness and pro-manufacturers bias to more or less maintain existing frivolous attitude to the safety of the consumers has been reflected in the clauses of this draft. Moreover it will be impossible for the small scale industries to follow this GMP, if the ammendment is converted to law. It will be impossible for them to establish full fledged in-house quality control laboratories. It will also be impossible for the old industries particularly those which are situated in the densely populated area or housed inside old industrial estates to expand the manufacturing area as required by the GMP. Therefore, the incoming GMP will have to compromise with the industry irrespective of their size and capability in the areas of quality of products and will in no way bring minimum safety and security to the consumers and workers of the pharmaceutical industry.

A Note

THIS note is to inform the readers of *RJH* that from June, 1988. I shall be moving from the category of Working Editors of RJH to that of the Editorial Collective. The reason for this shift is that for the past one year I have moved out of Bombay to a small village in Pune district of Maharashtra for a period of five to six years. I have thus hardly been a 'working' editor during this period.

It is only due to my persistent request that the other Working Editors have finally, and reluctantly, agreed to let me shift out. Moving out creates in me a feeling of deep personal loss because all the three Working Editors, as well as some of the comrades in the Editorial Collective of *RJH* are my closest friends. During the next five years I shall greatly miss the warmth and the intellectual stimulation that the RJH collective has always offered to me.

I shall certainly continue to stay within the Editorial Collective of *RJH* because I fully believe in the ideological perspective of the Journal and have no differences either political or personal with the form and content of RJH. I am sorry that I am not able to undertake more responsibility on behalf of *RJH,* much as I want to. And, I am aware that the loss is mine.

In solidarity

Manisha Gupte.

Medical Ethics

An Introductory Essay

gayatri singh

With the rapid advance in medicine and its increasing privatisation, the highest standards of ethical conduct are called for from doctors. It is for this reason that the medical profession is governed by certain fundamental ethical principles. By setting certain ethical principles a doctor's expertise is attempted to be harnessed for the needs of society. What are the issues which confront doctors when interacting with patients?

WITH the medical profession becoming increasingly specialised, the acquisition of higher medical education and knowledge has become the prerogative of the upper middle class, resulting in fundamentally altering the age-long close-knit 'family relationship' that existed between a doctor and a patient. Not only has the doctor become increasingly isolated from the needs of the patient, but the medical profession as a whole has miserably failed to extend its knowledge and facilities for the benefit of the public.

Overawed by the doctor's grasp of medical 'knowledge', and unable to comprehend the complexities of the medical world, the patient is placed in a hopelessly unequal bargaining position. The surrendering of the patient to the doctor has become complete to such an extent that treatment, even if unsafe, is not questioned. Being thus placed in a position where the doctor has virtual control over the well being of the patient it is not surprising that the doctor can, wittingly or unwittingly, abuse his/her superiority. As a consequence of this strained relationship the nagging question that a doctor is constantly faced with and which he has to ultimately is: whether the health and well-being of a patient should be given priority or whether private profit and fame should be the driving motive which ought to define the doctor's relationship with his/her patients. Doctors must perforce decide which interests out of the two should prevail and the taking of such a decision depends to a large extent on the personal inclinations of a doctor. Since a patient is not divorced from the rest of society, the doctor's personal views with regard to the mode of treatment of patients has raised important ethical questions like: Should drugs, known to be positively harmful be prescribed to patients without explaining to them their harmful effects? Should technology and research be promoted for purpose other than for remedying the health of patients? Should doctors aid police officials in issuing false certificate certifying the death of a person to be 'natural' when in fact the death is known to be the direct consequence of tortue inflicted by the police? Should doctors refuse to give emergency treatment to a person solely because it is a medico-legal case?

These are just a few of the many troubling issues, which doctors are invariably confronted with in their day to day practice while interrelating with patients. A doctor may choose not to answer these questions and wriggle out of a delicate ethical dilemma by arguing that the manner in which a doctor relates to his/her patient is basically a private matter. It has been argued that the setting of standards for medical practice, directly impinge upon a doctor's right to practice and hence no such standards should be artificially imposed. A doctor should be allowed to freely relate with his/her patients in the manner which he/she thinks is most appropriate. If a doctor uses the medical profession to maximise his/her profits that is the personal choice of the doctor which ought not to be interfered with.

Yet, though doctors may relate to their patients at a private level, the fact is that doctors play a vital role in preserving and maintaining the health of a society and the medical profession cannot be left to regulate itself for important life and death issues are involved. Since doctors do not operate in a vaccum the decisions that they take vis-a-vis their patients have a bearing upon how they see their role within the medical profession. A doctor does not relate only with the patient but assumes various roles which require him/her to take important decisions which may adversely affect others. Thus, when a doctor decides to perform an abortion, despite laws to the contrary, s/he is not only expressing his/her personal views on abortion but is in fact making a public statement as to whether persons have a basic right to choose whether to bear a child or not; conversely, by refusing to perform an abortion because of one's religious or personal views, one is clearly taking a public stand by *refusing* to extend one's services for performing abortions.

Considering the complex social issues that one is confronted with, it may be extremely difficult to distinguish between what constitutes medical morals and medical ethics. For instance, when does one's personal views become the concern of the public so that public intervention becomes necessary for setting standards with regard to a doctor's practice? With the rapid advance in medicine and its increasing privatisation, the highest standards of ethical conduct are called for from doctors. It is for this reason that the medical profession is governed by certain fundamental ethical principles however outmoded they may be today. By setting certain ethical principles a doctor's expertise is attempted to be harnessed for the needs of society. It attempts to lay down certain guidelines though vague, with regard to what ought to be 'acceptable social conduct' of a doctor.

Evolution of Medical Ethics

If we look at the history of the growth and evolution of medical ethics we find that it was the doctors who initially played a vital role in establishing and setting standards for their profession. It is for this reason that the personal views of the doctors got reflected in the constitution of medical ethics. As the public became increasingly aware of its rights within the health care system, higher standards of practice were sought to be imposed upon doctors, though the code of ethics followed by the medical community has remained virtually stagment and the changes have been far from

satisfactory.

The earliest and the first known medical code was the *Code of Hammurabi* (c. 1900 B.C.), which set out, amongst other guidelines for doctors, the mode of receiving payments from their patients. According to this code, payments should inter alia, take into consideration: (a) the results of the treatment; (b) the patient's ability to pay, and (c) the status of the patient. Though the concept of payment for professional services has undergone certain changes, the basic concept of "no cure, no payment" has been deprecated, in modern day medical ethics.

As medicine developed and became more complex, it became apparent that certain standards for the practice of doctors would have to be specifically outlined with a view to prevent malpractices. Thus, a code of ethics evolved, which is today commonly known as the Hippocratic Oath. This oath forms the basis, upon which all subsequent international and national medical ethics have evolved. It is interesting to note that this oath was not a product of any public outcry against malpractices, but received inspiration and support from within the medical community. The oath lays down the following ethics to be followed by doctors:

1. The medical profession is to be harnessed for the benefit of the public and the doctor must, to the best of his ability, do good to the patient.
2. Abortion and euthanasia are to be condemned.
3. The nature of doctor/patient relationship is outlined and to take advantage of the superior position of a doctor is disapproved.
4. Strict medical confidentiality is to be maintained.

A modernised version of the oath was introduced by the World Medical Association as the Declaration of Geneva, which was amended at Sydney in 1968. Certain general guidelines for doctors were outlined (which stressed the importance of the health of the patient and the belief that the doctor should not only practice his profession with conscience and dignity, but should devote his life to the service of humanity. Great stress was laid on confidentiality which should be maintained even after the death of the patient. Competition within the medical community was also strongly condemned. "Utmost respect for human life from the time of conception" was the advise given to doctors. The strong views of the medical community against abortion is clearly reflected in this declaration even as late as 1968.

This declaration provided the basis for a more comprehensive International Code of Medical Ethics which lays down the duties of doctors in general, namely that a doctor must maintain the highest standards of professional conduct and must practice his profession uninfluenced by the profit motives. The doctor must not do anything unethical like self advertising, collaborating in any form of medical service in which the doctor loses his professional independence or receive any money in connection with services rendered to a patient other than a proper professional fee. As far as the duties of doctors to the sick are concerned the International Code states, *inter alia*, that a doctor must preserve absolute secrecy and must give emergency care as a humanitarian duty unless he is assured that others are willing and able to give such care. As far as duties of doctors to each other are concerned doctors are prohibited from enticing patients from their colleagues and a doctor in advised to treat his colleagues as "he would have them behave to him". Though all the three codes, the Hippocratic oath, the Declaration of Geneva and the International Code of Medical Ethics are vague and general in nature, the basic principle underlying all these three codes is the subservience of profit to the motives of the health and well-being of the patient.

An international attempt at setting medical ethics with regard to torture and other cruel, degrading and inhuman treatment, has also been made. This statement is embodied in the Declaration of Tokyo, 1975. Since a medical doctor practices medicine in the "service of humanity" having the utmost respect for human life, he is expected not to "countenance, condone or participate in the practice of torture or other forms of cruel, inhuman or degrading procedures, whatever the offence of which the victim of such procedures is suspected, accused or guilty". Nor shall the doctor provide any premises, instruments, instances or knoweldge to "facilitate the practice of torture or other forms of cruel, inhuman or degrading treatment or to diminish the ability of the victim to resist such treatment." The doctor must also have complete "clinical independence in deciding upon the care of a person for whom he or she is medically responsible. This code for the first time lays international standards and calls upon doctors to take an unabiguous stand against torture, and inhuman treatment of persons. It is obvious, that this declaration is applicable not only to countries under dictatorial rule but equally to countries which operate under the facade of 'democracy'. For it is here that the services of doctors have a greater chance of being misused. Fear of losing their jobs in government hospitals or fear of being deprived of certain benefits and privileges may force doctors to give false evidence or wrongly diagnose the injury of a patient or issue false certificates upon instructions from government officials. To fall a prey to such practices is clearly unethical and the concerned doctor can be hauled up by the national medical bodies for 'misconduct'.

With the increasing growth of medical technology, new inroads are being made in bio-medical research which involve human beings as research subjects, and hence the need was felt by international medical bodies to set guidelines in this regard. The Helsinki Decleration sets guidelines for conducting medical research which are essentially diagnostic and therapeutic in nature as well as for those whose essential object is purely scientific. It declares that concern for the interests of the subject must always prevail over the interest of science and society, and "in any research on human beings each potential subject must be adquately informed of the aims, methods, anticipated benefits and potential hazards of the study and the doctor should obtain the subject's freely given informed consent, preferably in writing". Unfortunately, the Helsinki Declaration bases its recommendations on the premise that if medical progress is to take place at all it must rest, in part, on experimentation which basically involve human subjects. At any rate, the positive aspects of this declaration are being implemented more by their breach.

The Indian code of medical ethics is based upon principles and standards set out under various international codes mentioned above. It incorporate the basic principles with regard to: (a) Service to humanity, (b) Misuse of medical knowledge contrary to the laws of humanity. (c) utmost respect for life from the time of conception; (d) respect for the secrets which

are confided in the doctor; (e) upholding the noble traditions of medicine; (f) treating colleagues as 'brothers'.

The general principles under the code outline the character of the physician and his/her relationship to society. Advertising or solicitation of patients is specifically prohibited. Income from professional activities is to be limited to services rendered to the patient and remuneration to be received for such services should be specifically announced to the patient. A physican is prohibited from prescribing or dispensing secret medicine or other secret remedial agents of which he/she does not know the composition. Duties of doctors to their patients deal with emergency treatment, maintenance of strict confidentiality and provision of proper medical care. The code also deals with duties of the physician to the profession at large, to each other, in consultation and to the public.

The national as well as state codes provide for initiating disciplinary action against a doctor for breach of any of the specified medical ethics. The action may be brought before the appropriate medical council (national or state). The medical council may consider and deal with any form of unethical practice which may be brought before it although it may not appear to come within the scope of the precise wording of any of the categories mentioned in either the national or state codes. It is obvious that if an unethical practice is specifically prohibited by any of the international codes of which India is a signatory, the national or state medical council can take as action against the erring doctor. The appropriate medical council may award such punishment as may be deemed necessary or may direct removal permanently or for a specified period from the register.

At the national level there are various laws which govern medical ethics of the medical profession.

The Indian Medical Degrees Act, 1916 prohibits all persons, save certain specified authorities, from issuing or alleging that they are entitled to issue any degree or diploma in western medicine or surgery. The act is restricted to the western methods of allopathic medicine and surgeons, homeopathic, ayurvedic and unani practitioners being excluded.

The Pharmacy Act, 1948 allows for only those who have attained a minimum standard of professional education to practice the profession of pharmacy. The Central Council of Pharmacy set up under the act is empowered to prescribe minimum standards of education and approved courses of study of examination of pharmacists. Section 36 of the Act lays down conditions under which the name of a registered pharmacist can be removed from the register for e.g. if the name has been entered by error or on account of misrepresentation or if the pharmacist has been guilty of any 'infamous conduct' which includes breach of professional ethics.

The Dentist Act, 1948, contains provisions for the constitution of an Indian Dental Council which is empoowered to lay down minimum standards of training and Provincial Councils which are empowered to maintain registers of persons entitled to practice dentistry. Section 17A of the act empowers the Dental Council of India as well as the State Dental Councils to prescribe standards of professional conduct and etiquette or a code of ethics for dentists. Such regulations may specify which violations thereof shall constitute 'infamous conduct' or in other words professional misconduct. Since the State Dental Councils have powers to adopt rules of professional ethics, they vary from state to state.

The Indian Medical Council Act, 1956, gives representation to licentiate members of the medical profession and provides for the maintenance of an all-India register by the Medical Council of India which will contain the names of all the medical practitioners possessing recognised medical qualifications. Section 20A empowers the medical council (state or central) to prescribe standards of professional conduct and etiquette, and the regulations so framed may specify which violations thereof shall constitute 'infamous conduct' or professional misconduct. Under the act, the name of the medical practitioner can be removed from the register either on his/her own volition or if a misconduct has been indulged in. 'Misconduct' is defined as:

(a) Conviction of a registered practitioner by a criminal court for an offence which involves moral turpitude.

(b) Conviction under the Army Act, 1950

(c) Any conduct which in the opinion of the council, is infamous, in relation to the medical profession particularly under any code of ethics, prescribed by the council or by the Medical Council of India constiuted under the Medical Council Act.

For any of the misconducts an inquiry has to be conducted by the appropriate medical council, before any action against the doctor can be initiated.

Role of the Medical Council

Since the Medical Council is the governing body of the medical profession, its main function has been the protection of a doctor's interest, and moves into action only if the conduct of a doctor brings disrepute to the medical profession. Take for example the highy unethical practices indulged in by the Federation of Obstetric and Gynaecological Societies of India (FOGSI) which took upon itself the task of representing and promoting a particular contraceptive. The Federation had circulated letters to the medical community urging them to promote the use of *Today*, a contraceptive manufactured by Bliss Chemicals. (Report by Rupa Chinai, *Indian Express*, 5.4.1988). The Maharashtra Medical Council because of the publicity, was forced to act against Dr. Daftary chairman of the Medical Termination of Pregnancy Committee. Clause 30 of the Maharashtra Code of Medical Ethics clearly states that medical practitioners would be guilty of 'misconduct' if they associate with "medical agents or manufacturers in the advertisement of products of particular manufacturers." This is not the first time that a medical body like the FOGSI has been closely associated with drug manufacturers. In the public hearing on high dose EP drugs held at Bombay, FOGSI filed affidavits supporting the use of this drug despite the existence of voluminous evidence to show that the drug was harmful. High dose EP drugs are being promoted by various pharmaceutical companies and it is evident, by going through the affidavits alone, that the FOGSI in collaboration with certain drug manufacturers was promoting the drug realising fully well that the drug had been banned in certain western countries because of its proven harmful side effects. The medical council has not taken any action against the FOGSI.

With the growth and poliferation of pharmaceutical companies, the bond between doctors and drug companies has

become stronger. In order to promote a particular brand of a drug company, doctors prescribe medicines to their patients, which are either of no use or are patently harmful. The tremendous hold of the drug industry over the health care system in our country, was recently brought to light by the Lentin Commission. Another example of the proliferation of useless and spurious drugs in the fact that more than 20,000 kinds of non-prescription drugs are on sale in the Indian market. most of which are non-essential and about 25 per cent of them spurious. As against this, the WHO has prepared a check list of only 200 essential drugs. Though the medical council is fully aware of the unethical practices of doctors prescribing drugs known to be harmful and useless, why has the council not prosecuted the doctors and more importantly should not the medical council have powers to initiate proceedings against drug companies?

The research establishment, both private and government, also collaborate with drug multinationals in conducting human trials. Human experimentation by the medical community is justified on the ground that such trials are for the benefit of humanity. For example, experimentation by administering injectable contraceptive Net-pen, which has not been proved as a safe drug is being conducted on several thousands of Indian women, who are being used as guinea pigs without their informed consent. These trials are being initiated by the government's family planning programme. The Helsinki Declaration clearly states that no tests should be conducted on human beings unless they are proven to be safe and without obtaining the informed consent of the person on whom the experimentation is to be done. The Net-ten tests are in clear violation of this declaration. The governmental institutions are the most consistent violators of medical ethics and yet the medical council and courts have been hesitant and unwilling to take any action.

In the Bhopal case, the government and its research institutions have effectively suppressed all medical information pertaining to the after-effects of MIC. and the treatment to be given to the victims. For example, though the Indian Council of Medical Research (ICMR) prescribed mass detoxification to the victims, by injecting sodium thiosulphate, the medical community in Bhopal ignored this recommendation.

The recent scientific advances in the field of reproduction like amniocentesis, chorion villi biopsy (CVB) are calling into question the philosophy and values of medical ethics. Those techniques which were meant to detect genetic deformities are now being widely used for sex-determination. Not a single doctor has been prosecuted by the medical council.

These are just few of the examples where not only doctors but government institutions have flagrantly violated the various international and national codes. And yet nothing has been done and the medical system continues to devour and maim a large number of people.

The extent to which the medical profession will conform to proper standards of medical care will depend to a large degree on the development of the public's awareness of the issue. The basic rules of social conduct can be ensured only if the public maintains a constant and vigilant eye on the doctors in particular and the functioning of the health care system in general. It is only then that the doctors will be forced to abide by the highest standards of medical practice.

(Contd from page 87)

selective abortion of female foetuses could continue unabated. The callous and blatant attitude of the medical profession towards this question can be illustrated through a front-page advertisement appearing in one of the city's eveningers barely five days after the Maharashtra government's triumphant declaration of intent on January 1. This advertisement read in bold type, "Boy or Girl? Contact. . . clinic." A proposed legislation that will, in all likelihood ban such blatant advertising did not deter the doctor couple offering sex determining facilities. It must not be forgotten that, though pushed into a corner on several occasions, the medical profession refused to take an ethical stand before the government's declaration of bringing in such legislation. Apart from the high level of vigilance, a commitment from an ambivalent medical profession, faced with the loss of quick commercial gains, is a must.

(Contd from page 90)

the groups should utilise the avenues available to participate in the implementation process, in order to expose the hollowness of the bill.

The medical establishment had earlier argued that a law would force female foeticide underground. Now they have, in collaboration with the government, brought a law which can partially keep female foeticide above ground, within the purview of law. There is no alternative but to continue struggle against the medical practice of female foeticide.

[This Bill has been passed in the Maharashtra Assembly without any significant amendment in April 1988].

SCIENCE AS CULTURE
Edited by Les Levidow

Political forces shape science and technology: the practitioners, the research questions, the conceptual frameworks, the funding institutions that promote certain directions, and the official history of their progress.

The contributors to this collection take up several examples: 'Social Darwinism', the Copernican Revolution, dialectical biology, the export of hazards, nuclear politics in Yugoslavia, the tunnel vision of the sociology of science, and the lives of famous scientists.

Fee for Service in Maharashtra Hospitals

It is not surprising that the Government of Maharashtra has been the first to introduce fee-for-service medical care in all district and Government medical College hospitals from February 9 this year. The trend had started long back: the Municipal Corporation dispensaries and hospitals hiked the OPD case paper charges over a year ago with no significant resistance from any corner. But now the fee-for-service will be and is being charged at a higher rate not only for the OPD and indoor case papers, also for each component of the service availed of by the patient. The outdoor case paper now costs Rs.2 instead of 10 paise for seven days' treatment, and for indoor patients the charge is Rs.5 per day (in addition Rs. 3 per day are charged for diet). For laboratory investigations the charges are: Rs.5 for routine blood, Rs.10 for urine, stool, sputum, ESR, malaria and filaria, Rs.5 for MMR and screening, Rs.20 for standard X-ray. For operations, the charges are: Rs.120 for major operations, Rs.50 for minor operations done in minor OT., Rs.10 for minor operations done in the OPD without anaesthesia. For deliveries in these hospitals, family planning disincentives are applied: Rs.20 for third and subsequent deliveries.

The virtues of fee-for-service have been rigorously propagated in Maharashtra for the last one and a half decades. The political and economic crisis of the Indian rulers, which began to manifest itself from the late 1960s, was reflected acutely in the health-care sector. The experimentation primarily with the support of foreign funding agencies which led later to the formulation of international and national strategies for the primary health-care and the health for all had begun as early as the late 1960s and the early 1970s. All these experiments were meant to develop a strategy without radically changing the health-care structure and so also the social structure and without demanding any extra resources from the state to provide some basic health care to the people.

As these experiments grew under the 'care' of NGOs and voluntary agencies all over India, particularly in Maharashtra, they exerted a strong influence on government policy-making. Many of them attributed their success in people's participation to their policy of charging for services, albeit charging at low price. While attacking government policy of providing free services, it was argued that people do not appreciate services when provided free and there is a wastage of resources, as people misuse and overuse government services. They did not stop here. They even carried out some studies showing that the community is ready to pay for the services from the village health worker level to the hospital level. Thus evolved a strong case for the 'community financing' of health-care.

In this context, two points should be noted. Firstly, the majority of the NGO experiments were and are being carried out noy in the developed districts but in the underdeveloped areas (Jesani, Duggal, Gupte, 19). Therefore, in these areas the penetration of commodity relations is very pronounced. The NGOs' policy only took it further. Secondly, corruption and malpractices in the government sector are so rampant that they have already become institutionalised. The PHCs are no longer exclusive free service institutions nor were the district and the medical college hospitals before the February 1988 order. In a very significant number of them private practice by doctors both inside as well as outside the institution is the norm rather than the exception. In fact, about 25 per cent of PHCs and all rural hospitals and district hospitals officially allow doctors to do private practice, although not within the institution. Therefore, a fee-for-service atmosphere and value system has existed for long in the government sector. The health bureaucracy too believes in and encourages this state of affairs.

However, despite corruption and malpractice, poor were able to avail of some services, though it was second grade as doctors used to be more concerned about those patients who were either VIPs or used to fill their pockets. Now with the government becoming a 'private practitioner', even this second grade service is no longer available to the poor. The provision of providing free treatment to 40 per cent of patients is an eyewash, as it is at the discretion of the civil surgeon and the superintendent, who neither have inclination nor time to indentify such needy patients. Undoubtedly the government has in one stroke thrown overboard the fundamental recommendation of the Bhore Committee (1946) that health care should be available to people irrespective of their ability to pay.

Ironically enough privatisation of health

financing has take place in the context of the much lauded primary health-care and health for all. Certainly, privatisation does not necessarily and logically flow from the basic principles of primary health care. But when the PHC approach is articulated within backward capitalism which has historically, in our country, encouraged private sector through public sector resources, and at a time when the private health sector is attempting to expand its sphere of operation, it could generate a dynamic towards privatisation unless the PHC approach is combined with a vociferous demand for complete nationalisation of health-care services and allied drug and instruments industry.

Moreover the demand for low cost health-care must be made secondary to the demand for a National Health Service. In a climate where the private sector is allowed and given concessions to establish hi-tech medical care and the government hospitals in the urban areas—especially those also catering to the VVIPs—following the same line, people's expectation and aspiration to be treated with the best of medical tools will naturally increase. This is irrespective of whether the so-called best is really the best or not, rational or not and even appropriate or not. This climate decisively undermines the basis of primary health-care approach and it will be regarded as a second grade service by the people. Thus while one must continue to work for rational medical practice—even show to the government how resources could be saved by having rational medical practices in our hospitals (as against charging for services to meet demands)—unless low-cost medical care is propagated with a demand for an NHS, the PHS approach may well turn out to be self-defeating.

Economic and Political Weekly

A journal of current affairs, economics and other social sciences

Every week it brings you incisive and independent comments and reports on current problems plus a number of well-researched, scholarly articles on all aspects of social science including health and medicine, environment, science and technology, etc.

Some recent articles:

Mortality Toll of Cities—Emerging Pattern of Disease in Bombay: Radhika Ramsubban and Nigel Crook

Famine, Epidemics and Mortality in India—A Reappraisal of the Democraphic Crisis of 1976-78: Ronald Lardinois

Malnutrition of Rural Children and Sex Bias: Amartya Sen and Sunil Sengupta

Family Planning and the Emergency—An Unanticipated Consequence: Alaka M Basu

Ecological Crisis and Ecological Movements: A Bourgeois Deviation?: Ramachandra Guha

Environment Conflict and Public Interest Science: Vandana Shiva and J Bandhyopadhyay

Geography of Secular Change in Sex Ratio in 1981: Ilina Sen

Occupational Health Hazards at Indian Rare Earths Plant: T V Padmanabhan

Inland Subscription Rates

Institutions/Companies one year Rs 300, Two years Rs 575, Three years Rs 850

Individuals Only One year Rs 225, Two years Rs 425, Three years Rs 625

Concessional Rates (One year): Students Rs 125; Teachers and Researchers Rs 175
(Please enclose certificate from relevant academic institution)

[All remittances to **Economic and Political Weekly,** 284, Hitkari House, Shahid Bhagatsingh Road, Bombay 400 038. Payment by bank draft or money order preferred, Please add Rs 14 to outstation cheques for collection charges.]

A cyclostyled list of selected articles in EPW on health and related subjects is available on request.

Norplant: 'The Five-Year Needle'

An Investigation of the Bangladesh Trial

ubinig

Norplant, a contraceptive subermal implant was introduced for clinical trials in Bangladesh as early as 1981. However, partly because of resistance from conscious groups the trial was abandoned. Four years later, the Bangladesh Fertility Research Programme with other international organisations and a pharmaceutical company once again initiated the trial. This is a report of investigations conducted by a concerned group in Bangladesh.

NORPLANT is the registered trade mark of the Population Council for contracepive subdermal implants. It consists of flexible, nonbiodegradable tubes filled with levonorgestrel, a synthetic hormone of the progestin family. The implants are placed under the skin on the inside of a woman's upper or lower arm. The hormone is slowly released at an almost constant rate for several years.

Norplant implants come in two form. The first, called simply Norplant consists of six hollow silastic (silicone rubber) capsules, each capsule is 34 mm long, with a diameter of 2.4 mm, and contains 36 mg levonorgestrel. The ends of the capsules are sealed shut with silastic adhesive. This is the most widely used of the two systems. In Bangladesh, this system is being used.

The other system called Norplant-2, consists of two solid silastic rods, each 44 mm long. A total of 70 mg levonorgestrel is dispersed in the matrix of each rod. (PRS, 1987).

The promoters of the system are a coalition of hetrogeneous partners, (1) Population Council, New York, USA working through its International Committee for Contraceptive Research (ICCR) and (2) Leires Pharmaceuticals Company, Finland. In Bangladesh the preintroductory trial is being carried out by Population Council and Family Health International (FHI) through the Bangladesh Fertility Research Programme (BFRP).

Norplant Trial in Bangladesh

In this section we shall provide some information regarding the history of Norplant trial in Bangladesh which began as early as 1981.

The 16th meeting of the National Council for Population Control and Family Planning was held on February 7, 1981 at Bangabhavan and was presided over by the late president Ziaur Rahman. In this meeting, among other matters, it was discussed that, Norplant, a sub-dermal contraceptive which is easier and more effective than sterilisation should be introduced on a trial basis (National Council, 1981). Accordingly, a steering committee was formed on Norplant for introduction and examination of suitability and acceptability in Bangladesh. In August 22, 1981 a meeting of the subvention committee, Population Control and Family Planning Division, was held. The meeting considered the project proposal of BFRP on 'Clinical Study of Norplant Reversible Hormone Implant Contraception'. It was approved in principle and a sum of Tk. 7,43,000 including US 20,000 in foreign exchange was recommended for the project to be paid in phases. On October 4, 1981, BRFP put an advertisement in the *Bangladesh Observer and Holiday*, a daily and weekly newspaper respectively:

> A new birth control method
>
> **NORPLANT**
>
> *A wonderful innovation of modern science*
>
> - This method is for women
> - This can be implanted under the skin of arm
> - This will ensure sterility for 5 years
> - When removed, can have child again.
>
> Get more information:
>
> **Bangladesh Fertility Research Programme**
> 3/7, Asad Avenue, (1st Floor), Mohammadpur, Dhaka.

Immediately, there was resistance from conscious groups who pointed out the unethical aspect of the advertisement. An article was published on October 25, 1981, where several issues were raised. A brief text of the article is presented below:

> . . . So far as we know through reliable sources that the Technical Advisory Committee in Bangladesh did not approve its use in Bangladesh. However, the BFRP has successfully bypassed the Technical Advisory Committee and announced and advertised its use.
>
> It should be noted here that the BFRP was also the pioneer in using Depo-provera and Norigest in Bangladesh.
>
> Finally, some comments on the BFRP advertisement for Norplant.
>
> First, the advertisement syas "*Norplant-a wonderful innovation of modern science*" Hard to believe because we do not have any scientific evidence.
>
> Secondly, *the method is for use by women*. As women are politically less dangerous.
>
> Thirdly, *it will be implemented under the skin of the arm*. Will ensure identification for coercion.
>
> Fourthly, *this method will ensure infertility for five years*: A safe method for the population controllers and not the users.
>
> Fifthly, *when removed will ensure fertility again*: Nobody knows (Norplant, 1981).

The trial was then postponed, as it was known through sources in government that the Population Council was not interested in being involved with controversial issues. A group of 151 doctors and pharmacists made a petition to the minister for health and population control to stop such an unethical trial. This part of the information seems to be lost in the present document of BFRP. There is no mention of the attempt of the trial in 1981. The BFRP documents now shows that they have initiated the clinical trial on Norplant in February 1985 under the financial and technical assistance

from Population Council and Family Health International (FHI) (FERP, 1986).

In an article by Dr. Halida Hanum Akhter, the present director of BFRP, it was mentioned that the BFRP has initiated the study after obtaining clearance from the Directorate of Drug Administration "to assess the acceptability and effectiveness of the new method among Bangladeshi women through government controlled hospitals and clinics such as the Institute of Post Graduate Medicine and Research (IPGMR), Dhaka Medical College Hospital (DMCH) and Mohammadpur Fertility services and Training Centre (MFSTC)" (*New Nation, 1987*).

> Earlier BFRP had obtained clearance from its 19 member executive council headed by the secretary ministry of health and family planning and consisting of members from various government and non-government research organisations. University departments and ob gyn departments of medical colleges.
>
> The advisory committee was constituted by the Bangladesh government in February, 1985 to make major policy decision relating to the clinical trials and use of Norplant as a contraceptive, to decide the mode of Norplant study and monitor the acceptability of the new method of female contraception and to decide on the use of Norplant in large scale in the family planning programme cleared the use of Norplant in Bangladesh. . . .The BFRP initiated the pre-introduction clinical trials only after the World Health Organisation decided at its Special Technical Review in November, 1984 that the Norplant was an effective and reversible, long-term birth control method which has proved to be superior to all other reversible methods.
>
> It has been found by researchers that contraceptive pills containing progestin and more commonly used other reversible methods necessitate continuous motivational involvement by the user. In a country like Bangladesh this fact is more true than in the developed world. It is, therefore, necessary to introduce methods in Bangladesh which can continue to be effective for long periods without continuous motivation by Family Planning Workers. Norplant is perhaps the most effective method which is likely to prove successful here.

The articles does not say anything about the study on the safety aspects of the research. Again, when BFRP is quoting the WHO special Technical Review decision (which also says nothing about safety) it only emphasises the effectivity and the superiority over other methods.

The BFRP protocol of research does not have the objective of looking into the safety aspects of the method. An effective method means that the method can ensure birth control; but it does not necessarily mean that by being effective it is safe for user's health. The safety aspects are directly relavant for women's health, while the effectivity only deals with population control programme aspects.

It is interesting to note that even before BFRP undertook the trial in February 1985, the Third Five Year Plan had incorporated the use of Norplant. It says:

> This long lasting method has the potential advantage of not requiring day-to-day use and therefore may be particularly suitable for our *semi-literate* population. It is proposed to introduce this method initially on trial basis, and the programme for its wider use can be decided according to the experience of the trial (TFUR, 1985). Here again, the effectivity question is mentioned and is specially targetted towards the semi-literature population, in other words, the poorer section of the population, so that population control can be ensured.

The BFRP had started promoting Norplant even before the trial was completed. While the trial began in 1985, the BFRP started making the following claims:

> The Norplant contraceptive system is suitable for most women of reproductive age. (BFRP, 1986).

Norplant is a contraceptive system which is still under scientific investigation or trial. Because of the known and unknown health hazards of administering long acting hormonal implants scientists and women's groups all over the world as well as concerned individuals are resisting even the trial of this system. The trial was attempted secretly in Brazil. Later when it became a public scandal and had started facing resistance the experimentation was stopped.

It is important to briefly state the scientific status of Norplant. Here's a critique of the 'Facts About an Implantable Contraceptive' published in the *Bulletin of the World Health Organisation* 63(3): 485-494 (1985).

A. *Insufficient Animal Experiment*:

1. Levonorgestrol and the half as actived, l norgestrol isomer are used interchangeably. Only the investigations referring to levonorgestrol are relevant. The interchangeable use of the two substances is confusing, and it is not known how far results for one substance are valid for the other substance.

2. The comparison of the doses given to animals and humans is misleading because there are big differences in the bioavailability and terminal half lives of the drugs between different species.

Table 1: Bioavailability and Terminal Half Life of Drug between Species

Species	Bioavailability	Terminal Half Life
Rat	9	0.5
Dog (Beagle)	22-6	1.2-0.3
Rhesus Monkey	9-4	4.4-0.5
Women	100	26.4-72

3. Although it is accepted that the beagle bitch is an unsuitable model for studying progestagins, experiments with this animal are included and no replacement experiments were carried out.

4. In the majority of experiments d, 1/levonorgestrol was given by the oral route. The comparison with implanted doeses is misleading because there is a difference in bioavailability.

5. Experiments are included which were carried out for approval as an oral contraceptive.

6. Although the rat appears to be a poor model for the testing of implants (local sarcomas) it is nevertheless used in animal experiments.

B. *Insufficient Clinical Research*:

1. The effect of Norplant on lipid metabolism—the experiments carried out to date are contradictory. Fat metabolism is associated with the development of cardiac problems.

2. The relationship between Norplant use and an abnormal glucose tolerance test. (This was only examined in six women according to WHO report.)

3. The safety of long term use of Norplant.

4. The effect of Norplant on blood coagulation.

5. The use of Norplant during lactation. Its effect on the growth and development of the child.

6. The use of Norplant during pregnancy.

7. The effect of Norplant on the levels of testosterone and rostenedione. The experiments carried out to date are contradictory.

8. The effect of Norplant on systolic and diastolic blood pressure in the fourth and fifth year of use.

C. *Inadequacy of Relevant Area of Investigation*:

1. In general, investigations were carried out with young, healthy, non-smokers. By 'healthy' is understood: without cardiovascular disease, without diabetes (also preferably not in the family), not overweight, without liver disease. Common causes of this are alcohol and poor nutrition. Women who had used injectable contraceptives were eliminated from some experimental series. Thus, not a good cross section of the population.

2. Frequently results are compared with those of women who use oral contraceptives, instead of comparison with women who use no hormonal contraception.

3. Some side effects (although not frequent ones) were not included in the WHO report. More implants were removed as a result of 'other medical reasons' than because of menstrual problems (6.5 per cent of 5.6 per cent), while menstrual problems occur more frequently. Some of these side effects are depression (1 per cent), more then 10 kg weight loss (2 per cent in Thailand); and epilepsy. (study in family planning).

Therefore, the claim of suitability for most women of reproductive age is not based on facts and is misleading.

UBINIG's Involvement in Study

Since 1981 UBINIG has raised the question of ethics of the research which is conducted on human beings. There are specified guidelines for bio-medical research, which must be followed. But it has been observed that the research ethics was violated in several ways. UBINIG's main concern is the health of women and that women, specially the poorer women, because of their vulnerable condition, should not become the victims of such research. From this commitment UBINIG has always pointed out the lapses found in the research in order to improve the situation.

In 1985, UBINIG was informed of the trial on Norplant by a development worker working with women in the slum areas of Dhaka city. She wrote a brief account of her experience with the trial:

> One of our group members (Jahanara) had four children. She became pregnant again and was worried. She went to several family planning centres for abortion (MR), but failed. Finally she told me everything and sought my help.
>
> On 15th December, 1985 I took her to Mohammadpur Fertility Clinic for MR services. We were told that abortion cannot be done because it is already 11 weeks of pregnancy. But soon they said that MR can only be done if she takes ligation operation simultaneously. Jahanara did not want to take ligation. So she was refused by the centre.
>
> I, then, took her to the medical college and met with the counsellor. Jahanara told the counsellor that she would prefer to take an IUD (plastic coil) after the MR. She said that she would not be able to take rest at least for three days after the ligation operation. She has to work. So it is better not to do it now. Then the counsellor told her about an injection. I remembered the side-effects about injectables so I said injections have possible side-effects. The counsellor said: "You are talking about injectables with 2/3 months duration. But here is another injectable which is of 5 years duration. It does not have any side-effects.
>
> I was confused, because earlier I heard of Norplant which is of 5 years duration, but the counsellor did not say that it was Norplant. During our conversation, the counsellor opened up a form and asked Jahanara to put her fingerprint on the paper. I could read what was written in it, although the counsellor did not make any effort to read the text to Jahanara which was meant for her. It said: I am completely aware of the method of menstrual regulation. I know about the problem such as infection, bleeding and peforation of uterus and yet I have requested for the MR.
>
> Jahanara put her fingerprint on the paper without knowing what was written on it.
>
> Then we came downstairs. I saw that several clients were sitting, while two motivators were trying to motivate the clients. A doctor came out of the room and asked. "Did you find a client." The motivators said, "No". The doctor said, "Try to motivate them".
>
> I asked the motivators about the 5-year injectables. They said that it was called Norplant. They also informed me that it is given in the PG hospital, the medical college and Mohammadpur Fertility Clinic and through Dr. Firoza Begum. They also mentioned that Norplant was being given through some private clinics. I became very worried and went to the room where Jahanara had her MR. I told her not to take Norplant. The I went to the doctor and requested her to let us go on that day. We would come back later. In this way Jahanara was saved from Norplant.

After this, we tried to find out more about Norplant. UBINIG research team found that most of the clients in the PG hospital were being motivated for accepting Norplant. However, they were found to have been asked questions such as, whether the woman was a lactating mother or not. One Aya thought that the research team was there as client. She suggested that if they take Norplant, then they could be given Tk 30.00 [app. Rs 60] and some medicine during the first visit. The client could come back in case of any problem and would receive Tk. 30 and medicine. In the PG hospital, we collected a leaflet which was distributed to the clients. The leaflet said:

Facts About Norplant

1. Norplant is a new temporary family family planning method. It is effective for 5 years.
2. Its use is relatively easier.
3. It is given under the skin of the arm with an injection needle.
4. Generally the side-effects of this method are less than that of the pill.
5. It is 100 per cent effective as sterilisation.
6. The user can take out the norplant whenever she wants.
7. The return of fertility after taking out Norplant is after one year.
8. It is possible to carry out normal movement and works when it is in the body.
9. There is no need of taking any other method when the method is in use.
10. The doctor will examine the client before the method is given.

To know more about Norplant, contact the doctor

(Collected From IPGMR on December 24, 1985.)

If we evaluate the points mentioned in the leaflet, we find that it actually violates the ethics by providing false information to the clients. A few examples of the falsity of the information are given below:

Point 1: The claim of effectiveness is not completely true, because according to BFRP newsletter the rate of accidental pregnancies during the first year was 0.4 pregnancies per 1000 users. The WHO records indicate a gross cumulative pregnancy rate at 5 years of 2.6 per 100 women years. The annual pregnancy rate during the first 5 years ranged from 0.2 to 1.3. ('Facts about an Implantable Contraceptive', *WHO Bulletin* 63(3) p. 485-494 (1985).)

Point 2: Its use is not easier because it needs surgical approach to put the capsules under the skin. The WHO recommends that to minimise the risk of infection, both insertion and removal should be performed in a clinical setting. It is of utmost importance that sterile techniques be maintained throughout both procedures.

The above two examples also indicate the violation of ethics by trying to motivate women with false information.

We have tried to collect more information but were not

successful because of the non-cooperation from the research organisations. In November 1986, a conference was organised by BFRP on "Contraceptive Technology Update", among other issues. Norplant research was discussed. A preliminary report was presented by S. Firoza Begum. According to her report 600 clients were admitted under the study within the period February 1985 to April 1986, but the total number that remained in the period Jan-April 1986 was 187 i.e. 31 per cent of all those admitted. She listed a number of reasons for removal. (Table 2).

From the users' satisfaction point of view Firoza Begum had pointed out that 40 per cent have liked the method because it lasts for 5 years, while 30.7 per cent liked it for easiness. About 56 per cent disliked it because of its effects on the change in menstrual pattern. 82 per cent have said that they have received 'enough' information about the method, while 17.8 per cent have not. One wonders what 'enough' means. If the above leaflet is the only source of information it cannot reach all the users because many of them are illiterate.

UBINIG Study on Norplant Clients

We found out the clients of Norplant during our study on the injectables in urban slum areas. In the area of Mohammadpur, Tikkapara slum we identified women who have taken injectables. We also went to Basila village which is a semi-urban village and found a number of injectable clients. During the interview we discovered one injectable client with Norplant. The client told us that she has taken a 'five-year needle'. Then she showed her arm having the capsules. Gradually we found more women in the same village who have taken the 'Five-Year Needle'. We have interviewed 10 women who have taken Norplant.

Three centres were visted by the UBINIG research team in order to get information about the trial. These centres are: (1) Mohammadpur Fertility Services and Training Centre, commonly known as Mohammadpur Model Clinic or the Mohammadpur Fertility Centre; (2) Dhaka Medical College Hospital, DMCH; (3) Institute of Post Graduate Medicine and Research, IPGMR.

Table 2: Reasons for Removal

Reasons	(N=32) No	Per Cent
1. Pregnancy Related:		
Luteals Phase*	2	6.2
Planned Pregnancy	1	3.1
2. Change in Menstrual Pattern:		
Amenorrhoea	4	12.5
Polymenorrhoea	6	18.8
Menorrhagia	2	6.2
Irregular Bleeding/Spotting	5	15.6
3. Medical Reasons:		
Body Pain	1	3.1
Headache/Nausea/Burning Sensation	3	9.4
Loss of Libido	2	6.2
Weight Gain	1	3.1
Serum Hepatitis	1	3.1
Infection at Insertion Site	1	3.1
Jaundice	1	3.1
4. Personal Reasons:		
Husband Eent Abroad	2	6.2

* In these two cases women were pregnant at the time of admission.
Source: Report of Firoza Begaum (1986).

The information obtained from (1) Dr. Hosna Ara Ali, deputy director and Ms. Pervin (a family planning worker) in the Mohammadpur Model Clinic, (2) Dr. Kohinoor, gynaec specialist and directly working with the Norplant study in Dhaka Medical College Hospital and Ms. Nadira Begum, a family planning counseller in IPGMR.

It was known that about 616 women were given Norplant in three centres. Except in IPGMR the other two centres had 200 clients each, while in IPGMR it was 216. The counsellor reported that another 14 clients will be given Norplant within one month of the interview (i.e. January 1988).

Information received from Mohammadpur Model Clinic shows that the age range of the clients is between 18 and 40 years. The Norplant is given within 1-7 days of menstruation. Women who are not breast feeding their babies are given the method. All medical check-up is done for the clients so that no disease such as jaundice, hypertension, diabetes is found in her. If the clients fall sick after the use of the method then it is taken out and she is admitted to the hospital.

The follow-up is done within 1.3 and 6 months of insertion. Those who have taken Norplant have come from Dhaka mostly, although a few have gone to Chittagong and Comilla after the insertion. However, they have stopped inserting any further Norplant since last one year.

In the Dhaka Medical College, the criteria of the Norplant receipients in terms of age was same as the other two centres i.e. between 18 and 40 years. In addition to that, the gynaec specialist said that one should use Norplant after one child is born. The breastfeeding mothers should not use it, because according to Dr. Kohinoor, "the hormone which is in Norplant may pass from mother to the child through breastmilk and can cause harmful affects on the baby." In response to the question, how do they get the clients Dr. Kohinoor said, "When women come here for taking a contraceptive method we give them a leaflet where the good and bad effects of Norplant use are written. But the women must get the consent of their husband". About follow-up she said that each and every client has a card. If the women do not turn up for follow-up care then workers go and visit them at their homes.

No insertion is made without complete medical checkups. Those who have hypertension should not be given, nor those having jaundice and diabetes.

As for side-effects, the most common side-effect is amenorrhoea. "However, this is not a serious side-effect", she said. "It is better for the health to have amenorrhoea. Because it saves the blood which would have gone through menstruation every month. Therefore there is no chance of having anaemia. You know these women are already malnutritioned Norplant is better for their health." she added. According to her 95 per cent of the clients belong to very poor class. "They are responsible for giving 4 to 5 births each. Since they cannot remember to take birth control method, like pills, every day, long acting methods are better for them. On the other hand, women in the upper class are intelligent and can take any other method".

Finally she said, "In order to get a good th[illegible] trade off. If 2/3 women die what's the n[illegible]ning there is a tion will reduce and 70 per ce[illegible] problem? The popula- successful. In every bir[illegible]ent of our research has been bad sides. This [illegible] control method there are good and [illegible] nas, too."

The doctor in the PG hospital has only joined recently, so she could not give much information.

Every centre we visited referred us to BFRP. But BFRP refused to give information on the ground that we will 'misinterpret them'. We have requested the director in writing.

Profile of Norplant Users

Below we shall provide a brief picture of the users of Norplant in the village Basila, in Dhaka city. There were 10 women, who were found to take Norplant from Mohammadpur Fertility Centre.

(i) *Economic Condition*: According to the information available about occupation of the husbands of users, and by direct observation of their household conditions, the economic status of the users is poor (6) and lower middle (4). Those who are poor are working as boatmen, fish sellers, day labour and small business. The average daily income is Tk. 40.00 to Tk. 50.00. They have no land and have to depend on selling labour for earing their livelihood. The lower middle families are mainly engaged in small business such as rice and groceries. The families are also found to be involved in briek business.

(ii) *Education*: Eight out of 10 users are illiterate; one has read upto primary level, and another has got secondary education.

(iii) *Age*: Two users are in the age range of 15-20 years, three are in 26-30 years, one is in 31-34 years and four users over 35 years of age. The highest age was found to be 45 years, while the lowest age is 18 years.

The age was determined by our investigators by asking the user about her age; about the age at marriage; about her menstrual situation at the time of marriage and about the age of her first child.

All this information together helped the investigators to come to a figure for age of the user. This age information is more or less accurate. In the centres where Norplant is given, the age limit is said to be 18 to 40 years and is noted only by asking the user about her age. In our sample, we find that a woman over 40 years has been given the method.

It is interesting to note that the draft protocol of the Norplant study does not say anything about age of the users. Moreover, the preliminary report submitted by Firoza Begum does not mention anything about the age level of the 600 users of Norplant. The question is whether the researchers are not taking the issue of "age of the user" as an important criterion of the research, whereas Norplant as a "long-acting contraceptive" method must have a limit for age for the method to be effective.

(iv) *Marriage and Child Birth Information*: (a) Duration of married life: Six women had a long married life of 20 to 30 years, while others had between 10 and 20 years. Only 2 young women were married in 1981. It is somewhat related to the age of the user. Most of the users (8) were married at an age of 13 to 16 years, and only 2 were married at the age of 18 years.

(b) Number of living children and children ever born: The average number of children for all the users (N=10) is 43, while maximum number is 8 and minimum is one child. As is known from national statistics, the number of child births is higher than the number of living children. The average number of child births is 4.7 (the maximum is 9).

c) Age at first child birth: Three women have got children before they reached 15 years, while 7 had children between 16 and 20 years of age.

(d) Time gap of first child birth and marriage: Five women got children only after a year of marriage, 4 had between 2 and 3 years and one had 5 years of time gap after marriage before the first child birth.

(e) Average gaps between child birth: The average gap between child births were found to be 2.1 years, with 4 years as the maximum gap.

(v) *Information on Contraceptive Acceptance*: Except 3, seven users have accepted other methods before taking Norplant. These other methods are pill and injection. Norplant has been used as a method of switch from other methods or other methods were taken after Norplant use. This is shown in Table 3.

Table 3: Use of Norplant and Other Methods

Category	No of Users
I Norplant as the first method and no switch	3
II Norplant as the first method but switched to other methods	1
III Norplant after using other methods	6

That is most of the users have switched to Norplant as a change of contraceptive method from other methods. One woman in the category II has already changed from Norplant to other method such as pill. In category I, one woman has taken off Norplant and has not taken any other method. In category III, one women has taken off Norplant. Out of 10, the drop out of Norplant is 3.

Those who used other methods have started using the methods since 1976. The Norplant was given in 1985. Only one woman has taken Norplant in 1986.

(vi) *Present Health Condition of User*: We have taken weight, height, blood pressure, pulse, anaemia etc. as minimum indications of health condition of the user. We shall provide the information in terms of average and maximum and minimum figures.

Height:	Average	4.11	
	Maximum	5.1	N=10
	Minimum	4.9	
Weight:	Average	42.3 kg	
	Maximum	48.0 kg	N=10
	Minimum	38.0 kg	
Blood pressure:		90/60	N=10
	Minimum Normal Level		
Plus rate:	65-80 per minute	5	N=10
	More than 80 per minute	5	
Anaemics:	Normal	2	
	Mild anaemic	2	N=10
	Moderate anaemic	4	
	Severe anaemic	2	

(vii) *Health Condition before Use of Norplant*: We have asked questions whether they had any specific health problems before the use of Norplant, we got the following response.

There was no problem	8	
Irregular Menstruation	2	N=10

That is, women having amenorrhoea and irregular menstruation were given Norplant, which aggravated their problem

even further. We could not however get information on health conditions for which Norplant is contraindicated such as jaundice, diabetes etc. So we abstain from making any analysis of it.

(viii) *Health Conditions after Use of Norplant*: All the 10 Norplant users were facing problems since they have taken Norplant. These were as they have expressed.

"No menstruation since 1 to 1½ years."

"Once menstruation is started continues for 15 to 20 days."

"Irregular bleeding, spotting" etc.

In addition to this the other problems are loss of apetite, vertigo, burning feeling in hand and feet, body ache, weakness, leucorrhoea, etc. If we order the health complaints in terms of the frequency of reporting, then the following pattern emerges:

	N=10
1. Amenorrhoea*	10
2. Irregular menstruation	4
3. Burning sensation	3
4. Excessive Bleeding, White Discharge, Body ache	2
5. Tiredness	1

* Almost all the clients suffered from amenorrhoea for different periods of time and most of them developed irregular or excessive bleeding in between.

Here by amenorrhoea is meant long period without menstruation, even more than 45 days. According to some clients they had no menstruation for one year or more.

A few examples of the users' complaints:

(a) "After I have taken the "Six" (the needle), I felt aches in my body after six months. I cannot look up, I do not have any apetite, I am going to die. The menstruation is very irregular, and during last Shabe-Barat (a religious occasion) I had menstruation for 2 months at a stretch", Anwara Khatun (30 years).

b. "I did not get menstruation for 2 year since I have taken this 5 year needle. Now I have aches in my hands, legs; I feel weak, I cannot explain; it is a terrible feeling", Fulbanu (35 years).

c. "Since I have taken the needle, I get menstruation which continues for 12 + 13 days together. When I took the 3 month needle, I had regular menstruation but now I had bleeding; clots of bloods going at the time of menstruation. I feel pain in the body. I put kerosene oil on my body; when I go near the stove to cook, I see things double. I cannot go near the fire". Nawab Banu (38 years).

Three women who could not tolerate the problems insisted on taking the Norplant off, and finally could succeed in convincing the centre to take it off.

For health problems, the users have gone to the centre to express the problems, but they were given only 30 vitamin tablets and in some cases a prescription to buy medicine from outside. No other treatment was done from the centre. But they had to go to some doctor. For example 2 have gone to a qualified allopath doctor, 3 have gone to traditional healers, called the kabiraj, and one to a quack allopath doctor. Five women did not go to any doctor because they did not have the money to spend.

(ix) *How was Norplant Taken by Users?*: The users first heard of injectables, the 3 month dose, from the family planning workers but later they heard from the neighbours that there is a needle for 5 years. They heard that it was better than the 3 month injection so it would be better for them to take the 5 year needle instead of the 3 month one. From their village, it is difficult to go to the centre frequently, so it was better if they could have a method of 5-year duration. One woman said that every woman goes to take Norplant is asked to talk about the benefits of Norplant to their neighbour, and that they should send their neighbours to take the method. None of the user has mentioned that they were using the method as a trial. The only information which was given to the clients was that Norplant was a 'needle for 5 years'.

(x) *State of Lactation, Pregnancy and Affects by other Contraceptives*: We have received information which is vital before a contraceptive like Norplant is taken by women. Table 4 is the representaton of the situation.

Table 4: Status of Women before Taking Norplant

State of Client's Condition at the Time of Norplant Acceptance	Number of Clients
Breastfeeding	3
Pregnant	0
Already had problems due to use of other contraceptive methods	1
Both breastfeeding and affected by other methods	3
None	3

Six out of 10 women were breastfeeding out of which two women had a child below one year of age. One of these clients had her last baby with the age of 1½ months only. Four women were still breastfeeding their child even though the child was over 1 year of age. In Bangladesh, the average length of breastfeeding is about 18 months.

Table 5 shows that there is no sign of using Norplant as a trial, it is used as a contraceptive method, like the injectables, IUD etc. The clients are not included under the trial with their informed consent nor any proper care is being taken for the health problems of the clients. However, the centres are selectively doing urine tests for some clients and not all of them. It is assumed that they want to eliminate the cases where the women are not coming within 1-7 days of menstruation. By urine tests they want to be sure about pregnancy.

Here again, the evidence suggest that the rules for trial were not followed although the workers are found to be aware of certain rules. Violations are particularly made in taking informed consent, in the selection of clients for the method and in the follow-up care. Information on the monetary incentives for follow-up monitoring was received from IPGMR Hospital. The doctor told us that they give Tk. 20.00 to each client for motivating the clients for visiting the centre for follow-up monitoring. They also reported that the clients are given Tk. 50.00 at the time of first insertion of the method. While the centres try to motivate the clients to come for follow-up visits the clients reported the contrary. According to the clients, there was rather discouragement for reporting health problems. The centre workers are friendly in their attitude before insertion of the method, but afterwards 'they do not even want to talk'. The family planning workers at the centre do not appreciate the clients' health problems at all and they also do not want to take it off. Since the method is clinical, and the clients cannot take it off by themselves, they feel helpless and therefore have to go to the centre and plead for taking off the method. It is upto the decision of the workers whether it would be taken off or not. This is

a helpless situation for the clients.

The clients also become discouraged to go to the centre for follow-up care because they are not given any treatment. They are given 'slip' only i e, prescription. The centre workers says that there is no medicine for treatment of the clients.

Discussion

If the trial is for acceptability and effectivity, the methodology is inadequate to prove either. The research methodology is directed more towards getting women so that the method can be inserted. Women are not considered as a human and social being. Therefore, no information is being shared with her except the information which will only lead to the insertion.

Women who are motivated to take Norplant are supposed to be motivated with full knowledge of the method as a trial. This is not happening. This can be proved not only by the

Table 5: An Examination of Rules to be Followed for Trials

Rules	Whether It Was Followed by the Trial
a. Informing the clients about the method and that it is on trial	None of the sample clients know that the method was on trial. The information which was given to the clients was that: 'It is one of the contraceptive methods and it is of 5 years' duration'.
b. Informing the clients about the side-effects	Two clients were told that "there will be some disturbances in the menstruation cycle, either it will stop or may be there will be more bleeding. There will be no other problem". Two clients were asked to come "if there is any problem". One client was told that "if you take this needle, there will be no problem, but if you get sick, we will check". One client was asked to take milk, banana and other good food. Four clients were not given any information.
c. Taking consent of the clients after providing all the information	No information was found which will reveal that an informed consent was taken. The clients were not even told of the name of the method. Only one client knew that the method was called "Norplant" and the rest knew that it was a 5 year injection.
d. Pre-medical examination of the client	Urine test and blood pressure checking was done for 2 clients, weight and blood pressure was taken for 8 clients.
e. Medical support to clients having side-effects after taking the method	Six clients reported that when they went to the centre to report about their health problem, the centre gave them prescription on plain white paper and asked them to buy medicine from outside. According to a client, "I have gone to the centre 2-3 times, they gave us slips only and asked me to buy from outside. I asked them, why should I buy medicine from outside when I have taken the needle from here. I want my treatment to be done here. The big doctor told me that the govt. did not give medicine for us. If I talk about my health problems more, they suggest I go for ligation operation". One client was given 30 vitamin tablets, another client got pain killer tablets once.

Table 6: Discrepancy and Similarities Found in Information Given by Centre and Information Received from Clients

Centre	Clients
a. Norplant is given within 1-7 days of menstruation	All the clients reported of same time period after menstruation.
b. Women who are breast-feeding are not given the method	Six out of 10 users were breastfeeding at the time of taking Norplant.
c. Norplant is taken out as soon as any side-effect is noticed.	Three clients have taken out Norplant. But their experience is that the centre did not want to take it off for first 2-3 times. Then when they insisted further, then it was taken off. In the words of a client, "when I had problems, and could not bear it anymore, then I went to the centre, but they refused to take if off. They said why did you take it?" Next time I went and made a lie by saying that my two children are drowned in the river and my husband wants another child. This time they took it off. The rest seven clients are having side effects but the method is not taken off.
d. All pre-medical tests are done. These include checking of disease like hypertension, jaundice, asthma, etc.	The clients have reported only urine test, blood pressure checking, irregular p/v exam and weight as the premedical test done for them. But these were also not done for all the clients.
e. Norplant is given to women between 18 and 40 years of age.	One client was 16 years and one client was 45 years. The rest were within 18 to 40 years of age.
f. The follow-up procedure is the following: Ist follow-up after one month of insertion, 2nd and 3rd follow-up after three months of insertion. Fourth onwards follow-up in after six months of insertion. Dates of follow-up visits are written on the card. If they do not come then the centre workers go to the clients' houses to see how they are.	The clients reported that they are asked to go to the centre after every 2-3 months. They know that the date is written on the card, but they have not seen any worker coming to their houses for follow-up care.
g. A leaflet is made with the information of good and bad effects of Norplant. This is read out to the clients; and then if they decide to take it then the method is given.	No client has reported of such information
h. Women having post-partum amenohrroea, are not given Norplant.	All the 10 women who have received Norplant during normal menstruation cycle.
i. The clients must have at least one child at the time of taking Norplant.	The clients reported that they were asked about the number of children they have.
j. Those women who have taken pills, must wait six months before they take Norplant.	Two clients were taking pill before taking Norplant. One of them has taken Norplant only after 2 months of stopping pills.
k. Clients must get consent of their husbands before taking Norplant.	Only six clients have taken consent and four did not.

(Contd on page 108)

Obsession with Socialism

rohit j oza

I AM attempting underneath to answer some of Anant R.S.'s criticism (*RJH* II: 1-2, June-September, 1987) by quoting an article from the December 1987 issue of the Russian magazine *Sputnik*. The journal comments: "Problems posed by health service [in Soviet Union] of late have come in for criticism. The truth is that the health service has been obsessed by the quantity of services [the widely available and almost free medical care referred to by Anant] rather than quality of these services." Anant's reference to "these stupid civilisations [of capitalist countries] spending more on health-care" can be well answered by the *Sputnik* article and I quote "Health service has been dominated by conservatism in economic management, thus creating serious propblems". Further, the article says, "the success stories of principles of medical aid as practised in USSR should not be ignored. But what was good yesterday will not necessarily be found satisfactory tomorrow". As for Anant's attempt to locate "the indicator to find out what percentage of medical needs are being met and in what manner", the *Sputnik* article has quoted the USSR Minister of Public Health as saying, "we will dismiss specialists for whom medicine has been a random choice of career and who refuse to treat the job seriously". (And this, Anant, in spite of the Soviet Union's population of 1.2 million doctors—the largest number as compared to any country in the world.)

In the words of Anant: "A rough opinion in a proper direction is better than a precise obsessed opinion in a wrong direction." The "information" needed to "draw valid conclusions" is well provided in the *Sputnik* article: "By 1990 almost a million people will have died of lung cancer in the USSR and most of these smokers". (So much for the healthy Soviet way of life as compared to the unhealthy American way of life.)

With reference to the "wrong work environment and wrong social environment", Anant should note the following sentences in the *Sputnik* article: "A quarter of water supply is without adequate cleansing"; "from 1965 to 1985 the incidence of lung cancer doubled in Soviet Union"; "forty per cent of sixteen-year olds smoke"; and "medical specialists pay little attention to the propagation of a healthy way of life as a whole".

In the end, I would like to quote five more sentences from the *Sputnik* article to start, if possible, another 'Dialogue':

(1) "In Soviet Union, it is intended, by 1995, to double the volume of Pay Services available."
(2) "It is worth considering the question of large enterprises or big organisations paying at least partly for the treatment of their employees (workers)".
(3) "It would be just to levy a specific tax on smoking. Such additional charge (income) could be used for the treatment of smoking related diseases."
(4) "The present situation [in the Soviet Union] can no longer be tolerated by the party, the government and the people. Nor indeed by us in the medical profession."
(5) "The patient should also have a right to choose a doctor whom he trusts."

The Soviet Union is restructuring all spheres of its economy, culture and life. It is high time Anant also 'restructured' his obsessions. Remember, all that glitters is not gold.

(Contd from page 107)

10 samples but also from the discussion with the centre workers about their methodology. Therefore, it cannot be proved with the number of drop outs that once they realise the problems they are no more interested in it.

The follow-up monitoring is done to note down the problems but with little care of the clients. The problems such as amenorrhoea are found to be frequent, but the tendency of the centre is to justify the problem rather than giving remedies for it.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a radical or Marxist perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions in a neat handwriting on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (for issues). I am sending Rs._____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

Why Should We Learn to Read?

We are poor
very, very poor,
but we are not fools
That's how though we are illiterates
we are still alive

We tried becoming literate once,
We joined the literacy classes,
but felt after some time
that we are even more depressed.
that our understanding
of our situation
had not grown at all
Se we left the literacy class
because we are not fools.
only illiterates.

The people who taught us in the class know things
that we don't know,
in the same way as we know things
they don't know.
We have our own minds,
our own opinions.
our own ability to understand.
to question, to analyse.
We are not small children.
We are not fools, idiots, dumbells.
Just because we can't read
dosen't mean we don't know.

Perhaps that's something they can't comprehend
Yes—we are poor:
Not enough food to fill our bellies,
not enough clothes to cover ourselves,
and then there's the floods, the epidemics the riots...
But can education ever remove
these basic problems?
Will education feed us, cloth us?

We hear that the government has made schemes
to help us, the Poor
Why don't we know about them?
Will we be able to
increase our crop yield?
get interst-free loans?
get safe drinking water?
get our minimum wages?
These things are what we call' 'education',
That kind of education is relevant to us
(Not to you—but to us!)
If 'education' can offer us this
We will come.
If it is yet another broken promise
another fake hope
all we can say is

WHY DONT YOU LEAVE US ALONE?

—Satyen Moitra, New Delhi

One Small Step

WITH this issue we complete four years of crowded life. As we begin a new volume we would like to share with you some of our experiences, some positive and some not so, in producing this journal. Also, we would like to collectively recollect how we began and why we launched a health quarterly at all in the first place.

As in any such venture, we too had some broad objectives in mind when we began. These objectives were evolved in response to a need many of us felt for such a platform in the context of the time. In the course of four years these objectives have themselves been re-examined — which we believe is a positive development. No journal can hope to survive without being conscious of changes in its milieu. At the same time it cannot afford to adapt itself too rapidly to every movement in its reference fabric. This creates a certain tension, the nature of which may be different for mainstream publishing and for the alternative media. *RJH* has generally been able to cope with this tension and work within it. Often some of the changes we make are mooted by pragmatism, and may not appear to further our goals. And this is why we are very much aware of the need to reflect on whatever has happened to us. This is not so much an exercise in self-criticism as a process of sharing our problems — which we are sure many other similar journals have experienced — and learning to deal with them.

In 1983 many of us independently began to feel the need for a forum for discussion and analysis of health issues from a left, marxist perspective. For one thing, since the 70s diverse groups with differing political and ideological perspectives had began to work in health as part of 'development' activities. Individuals in these groups through their work and exposure to ground realities had become sensitised and come to feel the need for a substantial radical critique of health. Also, political activists through their involvement in or exposure to health issues of working people had been forced to realise the importance of health in all its aspects to the practice of politics. Yet another factor was the emergence of the people's science movement, which although it had not at that time taken health as a major focus of its activities, had generated a sharp awareness of the need to critique establishment science including medicine.

What did we understand by a marxist approach to health and medicine ? As the editorial perspective in the first issue of the periodical pointed out, we meant an "analytical approach which takes a historical materialist and dialectical view of the health of people and the medical care system in a given social order." From this standpoint health was considered a part and consequence of economic, political and socio-cultural development of society. That is, "the problems of health and health care system reflect the problems of the dialectic of production forces and production relations and the broader social order based on it." At the same time we also acknowledged that there did not exist "one single marxist analysis — an all correct perfect line so to say of health and medicine." What the periodical hoped to do was to facilitate a continous interaction at the level of praxis amongst the different trends within the marxist movement.

However, we also agreed that there were other approaches or strands of analysis which had contributed to a radical understanding of health and health care. One such was the Ilichian which locates problems not so much in the socio-economic formation as in the bureaucracy and in the centralising tendency of capitalist development, faulting rather the trends towards industrialisation and urbanisation rather than the socio-economic system that engenders it. Similarly, the women's health movement in the west had pioneered the critique of the ideological structure of health care and the medical establishment and in doing so had rewritten in many ways the history of medicine. These we felt, would contribute to the development of marxist analysis of health.

But why did we need a separate journal for fulfilling these objectives? Couldn't existing left — journals or health periodicals serve the purpose? This was indeed an important issue since we did not want to merely add to the large number of periodicals unnecessarily, and secondly, many of us though not all, had our introduction to health issues in forums such as the **medico friend circle** which published some kind of periodicals. As the first editorial made clear, while other health periodicals would always remain useful in introducing individuals to a critical perspective on health, it may not be possible for them, or even appropriate, to initiate and continue a debate with a coherent political perspective, such as a marxist one. While the richness of the interaction between ideological perspective could not be underemphasised, the development of a marxist approach to health through these journals may not be feasible. As for other left oriented journals like the ***Economic and Political Weekly***, it was felt that since they covered all aspects of the analysis of society, it would not be possible for them, nor may they be so inclined as yet, to devote space to discussions and debates on health issues.

Thus was launched with great trepidation, the first issue of the ***Socialist Health Review*** in June 1984. In that one year not only had a collective of health and political activists from various parts of the country been formed, but we had also collected a small fund to cover costs through individual donations and pre-publication subscriptions. The response certainly surprised us and after the first few issues we were quite overwhelmed — we now have very few, a dozen perhaps, of the first issue on 'Politics and Health' and a few more

of the other issues except the second one, on Women and Health, and that was because it was reprinted with the help of a donation from a friend and well-wisher.

But even then, in spite of our euphoria, we recognised that if this response indicated anything at all, it was the need for such a periodical. And also that our survival was in equal parts due to the support of our readers many of whom encouraged us in several ways by recommending ***SHR*** to others, collecting subscriptions, sending donations and most importantly, writing enthusiastic letters to us and other factors, not the least of which was our 'discovery' of our first printers, **Omega**, who shared our burden in producing the journal, not only because they were such professionals, but because of their philosophical and ideological orientation.

For the first two years, ***SHR*** had a comparatively smooth run — there were of course financial problems, 'administrative' as well, because there were so few of us wanting to do so much (!) and other day-to-day troubles. (On one occasion, the production of our issue was held up because of a transport strike, and for the moment whatever the nature of the demands of the strikers, we certainly did not feel very sympathetic!) Then came the problems in our third year.

We can't help wondering at this point if this isn't quite typical of this kind of publishing. And is there a lesson in all this? That unless the skeleton structures for functioning are formalised in the first few years, the natural decline of enthusiasm in the later years will affect the activity drastically. We did try to do this with the ***SHR***. For instance, it was decided that the topic for each of the four issues would be decided well in advance. The editorial perspective, whether written by one of the collective or a 'guest', had to be circulated nine months in advance of the issue date. This would give enough time to organise a good collection of articles on a particular theme. This is how we have been functioning more or less, until recently and we hope to revive it very soon.

There were of course, many critical comments, perhaps the most important one, after the first issue, that ***SHR*** read too much like a 'high brow' journal. That is, the articles assumed a degree of familiarity with marxist analysis which may not exist among most readers. This led to the use of marxist terminology without explanation which sounded like jargon. This was a serious problem — either we could decide that those who did not have a grounding in marxist analysis were not our target readership and so we could not cater to their needs, or, we could attempt to 'dejargonify' the articles and in fact introduce the marxist approach to social analysis through the discussions on health issues. Almost unanimously we opted for the latter. We have attempted various ways of getting over this problem by trying to use a minimum of marxist terminology without damaging the analysis, and by presenting a mix of articles, some of which were more rigorously marxist than others. (Sometimes of course, we wonder if we have fallen between two stools because we receive our share of criticism on this count from both groups.)

Together with other problems, we discovered that for some reason we could not register the journal under its name. Of all the near -***SHR*** names we proposed, we were allowed to use the ***Radical Journal of Health.*** In January 1986, at a meeting of the collective, it was decided to set up a trust, which happily we could name the **Socialist Health Review Trust** to undertake the publication of ***RJH*** as one of its activities. We also decided to collect a corpus fund, introduce a life subscription and raise our subscription rate marginally. So far we had been subsidising the journal through donations collected in the first year or so but we could no longer do so. Moreover, this was also the time when **Omega** ran into a variety of problems and could no longer print ***RJH***, which meant that our cost of production would also go up. Fortunately we found friends again, in the shape of **Bharat Printers,** Bombay and the ***Economic and Political Weekly*** who undertook to print the periodical and typeset the matter and produce layouts respectively painstakingly, at reasonable cost, bearing with all our now haphazard time schedules. With this issue the journal is now back with **Omega** and may this be the last word on the subject!

The journal has touched upon a variety of issues some of these have become the focus of debate. But others which had been consciously raised with a view to generate discussion, such as the issue of the socio-economic roots of the prevailing practice of witch hunting in tribal region of Maharashtra, failed to elicit much response. We have come to realise that the 'objective conditions' have to be right even for initiating debates — they need to be live and day-to-day concerns. While theoretical issues do get a response the debate does not continue for very long. This may also be due to the fact that academic interest in health issues may be of recent origin in India.

To any retrospective reader it may appear that the ***RJH*** has glossed over three health issues which have been very much the focus of public attention in the years of our existence : pharmaceuticals, the Bhopal disaster and the campaign against amniocentesis and sex determination techniques. Although we did carry a couple of articles on Bhopal, we have not had a sustained focus on it. Similarly, while the ***RJH*** has published reports and discussion pieces on pharmaceuticals, it is only in our last volume that we have carried substantive articles on the drug policy or for that matter an entire issue on pharmaceuticals. We have done a little better on the amniocentesis campaign our very second issue carried an article on the topic and a recent number did as well; but nevertheless, we did not in a major way, contribute to the ongoing struggle to obtain a ban on the technique. Perhaps this needs an explanation of sorts.

Early on, it was felt that we did not need to publis'something' on every issue, unless we had something to say (

Health Care Beyond Apartheid

Economic Issues in Reorganisation of South Africa's Health Services

max price

The consequences of apartheid for health policy in South Africa are profound. Racial differences in health status and the allocation of health care reflect the inequalities of power and wealth produced by the political economy of apartheid. Furthermore, health policy is itself instrumental in furthering apartheid goals. It might be tempting then, to rely on the demise of apartheid and subsequent democratic redistribution of power and wealth to redress the fundamental inequalities in the provision of health care. Yet, as has been seen in Zimbabwe for example, radical political change is not sufficient in itself fully to transform the health services. Likewise in South Africa, it will require more than the mere removal of apartheid policies to attain health for all. This article analyses the economic organisation of health services in SA, so as to identify various structural obstacles to the provision of health care for all, which could well survive the demise of apartheid. The article analyses the proposed options for reorganising the economic structure of the health services to decide whether they make economic sense and to indicate the likely consequences of particular choices. It does not assess the political possibility of their implementation.

The article is abstracted from the author's Master's dissertation to the London School of Hygine and Tropical Medicine, published in full in ***Critical Health****, March 1987.*

IN 1944, in South Africa (SA) the Gluckman commission proposed the establishment of a comprehensive national health service. Few of the commission's recommendations were implemented. However, while not committed to the principle of a national health service, the Nationalist government steadily increased its control over the health services during the 1960s and 1970s. Since the late 1970s the trend has turned towards greater privatisation. This has recently been accelerated by the state's current fiscal crisis, combined with escalating health care costs. There are also strategic political and ideological reasons for the change in the state's policy towards increasing the number of people who use private sector providers. This trend has been supported by various private sector organisations, think-tanks, companies and professionals. On the other hand, there is also a growing concern about the inadequacy of the present health services amongst some professionals and political organisations, many of whom have called for the establishment of a national health service. Thus the debate on the choices to be made regarding how the health services should be financed, has again flourished.

Not surprisingly, it is often emotive, and positions are taken primarily because they are in line with the broader ideologies of the authors. But more importantly, when economic arguments are marshalled, they are frequently confused. Choices are crudely defined, since the options of 'privatisation' and 'nationalisation' are presented as if they were each a single uniform phenomenon. On closer examination however, it will be seen that the nature of each is more complex, and defined by a range of possible combinations rather than one essential feature. The choices in the economic reorganisation of the health services, therefore, comprise a series of options which should be examined discretely.

The effects of the system of apartheid on health and health care have been extensively researched and debated. These studies have focussed largely on those aspects of the health services that fall under direct government control — viz. the public health sector. There has been very little research or debate on the health service as a whole and in particular, its economic structure. Recently, however, this debate has flourished.

Although for most of the 1970s the government seemed to view the provision of health services primarily as an obligation of the state, and seemed to tolerate the private sector with some suspicion and a good measure of control, the recession and fiscal crises of the late 1970s and 1980s have resulted in a dramatic shift of attitude:

> Curtailed by the lack of resources, especially financial, ... a more active process of privatisation of health services is indicated. Dr. Francois Retief, Director General of the Department of Health and Welfare, 1985. [2]

> We will have to guard against being compelled to move away from the free market system. (The Minister of Health and Welfare in parliament, March 1984.) [3]

> Health authorities must not be seen as an infinite source of health facilities and medical care. More people should be able to make use of private health facilities as their economic circumstances improve. (Dr. M.H. Ross, Department of Health and Welfare, 1982.) [4]

The government appointed the Browne Commission of Enquiry into the Health Services in the Republic of South Africa in the early 1980s. Although it has recently submitted its report, this is not yet published at the time of writing. Since 1980, SYNCOM (PTY) Ltd, a private sector 'think-tank' organisation, has received several commissions to research the future of health care services in SA from the Pharmaceutical Society of SA (PSSA) and the Health Strategy Group (HSG). The HSG is composed of the Medical Association of SA, the Dental Association of

SA, the Chemical Manufacturers Association of SA PSSA, the Propriety Association of SA, the Representative Association of Private Hospitals, and the SA Nursing Association. In August 1985, the department of health convened a meeting at which representatives of the HSG, industry, academia and the public sector deliberated on the options for privatisation of health care. Out of this, four working groups were established which presented their consolidated report in February 1986.[5]

Between August 1985 and June 1986, the South African Medical Journal (SAMJ) carried 14 letters, an editorial and an opinion column on the subject of whether or not a National Health Service (NHS) would be appropriate for S A. So the future economic organisation of health services in South Africa is very much on the agenda.

The 'Ideological' Arguments

Much of the debate simply reflects participants' vested interests and ideological tendencies, with little attempt to explore the consequences of proposals honestly and rationally. For example, one opponent of NHS, in a letter to the South African Medical Journal (SAMJ), claimed, "They (the advocates of NHS) are simply advocating socialism", as if that were sufficient reason for his opposition. Far more disturbing though, is the following allegation by SYNCOM about a report it prepared for the HSG in 1982 (known as the SYNCOM III report): "The draft to the final report contained chapters on the future role of the Associated Health Service Professions, on the changing scientific paradigm, and on the need to shift the incentive in health care from the curative aspects to primary health care with emphasis on life styles and prevention... It was unfortunate that most of these chapters and observations had to be deleted, since they were perceived to clash with vested interests."[7] And, on the other side of the debate: "In our view, the right to health implies provision of health services which are free, ..."[8] There may be good reasons why some or all people should not have to pay for health care at the point of service, but this has to be argued and the consequences examined, and certainly does not derive automatically from the premise that health is a right.

The examples of these arguments which follow are given in order to illustrate my contention that they are confused because of the analytic approach they adopt. The substance of the arguments will only be assessed later, since the point here is only to justify the presentation of an alternative analytic framework.

Although presented with many minor variations, most of the arguments for privatisation are covered in the report of the four working groups on privatisation and deregulation, and may be summarised as follows:

1. As the demand for health care, and health care costs escalate, the government and taxpayer will not be able to afford the health care bill. Privatisation reduces the costs to the state of health care because:

(a) Privatisation shifts this burden from the public sector to private individuals. The implication is that because private health care is not provided free, patients have to pay for it and therefore they carry the costs, not the government.

(b) If people have to pay for health care, the tendency to overuse health services can be reduced considerably.

(c) Since all parties are agreed that a minimum level of health care must be provided for the indigent, the aged, the chronically ill etc, where necessary the government should subsidise the individual, not the institution. This is claimed to be cheaper for the government because private providers in a competitive market are more efficient than bureaucratically controlled, non-competitive public providers.

2. Privatisation permits a range of levels of health care to be offered by providers. This not only increases consumers' choice of provider, it also permits discrimination, or rationing of health care along non-racial lines, thus depoliticising the issue.

3. People attach more value to services for which they have to pay.

Argument 1(a) is concerned with the possibility of raising funds by making private individuals pay to use health services, thus easing the burden on the state. Yet, hospitals do not have to be privately owned, nor do doctors have to be in private practice for this to occur, since such charges could quite conceivably be made for publicly owned services. Thus this argument relates to methods of paying for health services (public versus private sources of funds), not the pattern of ownership of services (the provision of services by private, independent health workers and facilities).

Arguments 1(b) and 3 are concerned with reducing the demand on the health services, using fees as a disincentive to patients so that they do not use the services 'unnecessarily'. These incentive effects on demand for health care depend on the use of user charges, third party systems of payment and other factors all related to the methods of financing health care, not the pattern of ownership of health services. For example, if patients have 100 per cent health insurance, then there is much evidence that their demand for health care increases, regardless of whether they are being treated in the private or public health sectors.

Just as public facilities can charge for their services, public funding can be used to pay private providers, as is suggested in argument 1(c). This argument is obviously concerned with a different sense of privatisation, viz, multiple private owners of health services rather than private sources of funds.

Argument 2 is about rationing scarce resources and the consequences for equity. Privatisation here refers to a particular pattern of ownership, viz., multiple providers; a particular method of financing, viz., private payment via

'user charges' or voluntary health insurance; and a particular form of remuneration of providers, viz., on a fee-for-service basis. Only with such a combination can the quantity and quality of service be varied according to how much a patient is willing to pay.

Much of the confusion in the debate on privatisation results from the failure to separate out three distinct aspects of privatisation: (1) private sources of funds; (2) payment of providers on a fee-for-service basis; and (3) private ownership of services. More generally, it is necessary analytically to recognise three distinct components in the economic organisation of any particular health service. These components are: (1) Methods of financing health services, i.e. how funds are raised to pay for health services; (2) Methods of remuneration of providers; and (3) Patterns of ownership of the health services.

When we turn to the international literature to throw some light on the debate about the economic organisation of health services, we find similar confusions arising from the same analytic failure to disaggregate the components of the economic organisation of health care as was found in the South African debate. Two examples are examined here to illustrate this.

Debate About Private Practice

In an article entitled 'Private Medical Practice: Obstacle to Health For All' Roemer identifies the following problems associated with private practice: (1) perverse incentives leading to unnecessary investigation and treatment, and escalating health service costs; (2) inequity resulting from the inability of lower income patients to afford fees to cover treatment costs; and (3) maldistribution of medical manpower caused by doctors' attempting to maximise their income by moving to areas where demand is high, i.e. where there are large numbers of people who can afford private medical fees.[9]

But are these problems endemic to private practice or do they apply to a particular form of private practice? If the latter, how can we identify what it is precisely about that form so that it can be selectively altered? I will take the problems Roemer identifies in turn.

1. The problem of perverse incentives and escalating costs arises because, in the health care market, the supplier is an important determinant of demand and therefore perfect competition fails. This problem may be aggravated when the provider is reimbursed on a fee-for-service basis, such that the more expensive the investigations and treatment, the more the provider benefits. As I will show later if private practitioners were paid on a capitation basis, whether by the patient directly or by the government or other third party, the perverse incentives would disappear although ownership of the services would remain private. In other words, the problem needs to be analysed by focussing on the method of remuneration of the provider since this is not inherent in the pattern of ownership (i.e. private practice).

2. Unequal access to health care due to inability to afford fees is mainly a problem for poor people who do not participate in any risk sharing scheme. In Western Europe, where 90 per cent to 100 per cent of the population are covered by social security, the inability of the poor to afford the fees of private health care is largely solved. (This is not to say, of course, that non-fee costs, utilisation, quality of care or distribution of burden of financing is equitable.) Again, the point here is that the criterion in this discussion, equity, relates specifically to the method of financing, rather than to the institution of 'private practice'.

3. The maldistribution of doctors in favour of the urban rich again depends primarily on the method of financing. For example, if private, self-employed doctors were paid an adequate fee-for-service by the government on behalf of the poor (i.e. by subsidising the individual), they might move to areas where they could maximise the number of patients per doctor. This could produce a reasonable distribution of doctors. The maldistribution of private practitioners is more accurately attributable to whether private or public sources of finance are used, than to how they are reimbursed, or the pattern of ownership.

Thus we can only make sense of Roemer's criticisms, given a strict definition of 'private practice' as entailing self-employed providers, dependent on fee-for-service for their income, where the fees are paid by patients with no risk sharing arrangements or third party payment systems. Roemer probably intended this definition. However, as the responses to his article exemplify[9], others may not accept such a strict definition and the different meanings of 'private practice' (e.g. direct payment by private individuals, competing privately owned practitioners, etc.) are one source of confusion in the debate. Yet this could be readily overcome by making one's definition explicit.

The more serious criticism though, is that the discussion fails to recognise that the economic organisation of health care (in this case, private practice) has three analytically distinct components viz. financing, remuneration and patterns of ownership. The failure to disaggregate the institution into its component parts masks the fact that judgements made about the institution as a whole, are in fact the result of judgements about one or other component of the institution. It is this failure to apply evaluative criteria to the separate components individually that results in much of the confusion that surrounds debates about the pros and cons of different ways of organising health services.

One way in which authors frequently deal with the conceptual difficulties that arise, is by apparently restricting their discussion to the first component — the financing of health services. However, their failure to identify the other two components often results in the de facto inclusion of the latter under a discussion of 'financing',

and the same confusion recurs. Zschock, for example, categorised the possible ways of financing health services as follows:

(a) Public and quasi-public sources — general tax revenues; deficit financing (including foreign loans); sales tax revenues; social insurance; lotteries and betting.

(b) Private sources direct financing of health care by employers; private health insurance; charitable contributions (including foreign grants in aid); direct household expenditures for health; communal self-help.[10]

Although these categories appear to relate only to financing, the discussion that follows this classification suggests otherwise. For example, with respect to general tax revenues, Zschock argues that "to increase significantly the proportion of general tax revenues allocated to health care ... would imply a movement towards increased socialisation of the health sector by providing free or low cost health care services for most or all members of society."[11] Yet there is no necesary connection between the extent of government funding (a financing issue) and the socialisation of the health sector (which concerns patterns of ownership, if socialisation means the extent to which health workers are employed by the state). Public funding very frequently goes to the private sector directly as fees (e.g. Medicare in the US), or as subsidies to social security, or as capitation fees to GPs. The methods of remuneration, the patterns of ownership of the health services and the various combinations of financing methods are all separate questions.

Social insurance or social security is another example of confused debate. Some authors do attempt to distinguish different forms which social security systems might take, e.g. direct (employing health workers and owning facilities) and indirect (paying independent private practitioners and facilities), multiple or single providers. [12,13,14] Abel-Smith makes the point that the many problems attributed to health insurance are not intrinsic to health insurance as a system of financing services, but to other associated features — e.g. in Europe, the fee-for-service remuneration system, and in Latin America, the separation from the ministry of health and the competition among the many social security schemes for scarce personnel.[15] Thus analysing social security as a method or source of financing is confusing unless the point is to show that very little can be said that is true of social security systems in general. Once again, the analysis would be facilitated by disaggregating the three components.

An Alternative Framework

The left hand column of table 1 sets out an alternative framework for the analysis of the economic organisation of health services. This has firstly been divided into its three component parts. Secondly, within each component a number of possible methods are identified. The methods within any component are not mutually exclusive, and frequently occur together in the same organisational form. For example, private health insurance may require co-payment and thus the method of financing includes user charges. For the sake of continuity with the conventional taxonomies, the table attempts to indicate the links between the categories used in this analysis and conventional categories (in the right hand column). Also in the right hand column are the institutional forms which usually manifest the particular method of financing, or remumeration, or pattern of ownership.

Increasing Finances For Health Care

In the debate on health care financing in SA, privatisation has most frequently been supported on the basis of the claim that it will result in more funds being made available for health care. The argument, typical of that common in the international literature, usually runs something like this: The level of resources that a government can raise and devote to health services will always be less than is required to meet the health needs of the whole population. (Indeed, even if the whole GNP were allocated to health, this would not meet the total needs). If, however, there are individuals or groups of individuals who are willing to pay more for better health services than can be provided through the public health sector, this should be encouraged because it can release the public funds spent on these individuals. Thus total resources allocated to health services can be increased, and public health expenditure can be concentrated on the poorer members of society.

This type of argument in favour of privatisation depends on a number of assumptions which are only valid under certain conditions. The following discussion identifies the conditions under which each assumption would hold, and shows that these do not obtain in SA at present. It suggests how these conditions would have to change in order for privatisation to make economic sense as a means of increasing the total financial resources devoted to health care.

First Assumption: Public and Private Methods of Financing are Independent

The first assumption is that the increased expenditure by other sectors (private individuals, medical schemes, employer- provided services) releases public expenditure that would have been spent on the beneficiaries of those sectors. Thus, for example,

> (The private sector) is self-perpetuating and independent of government finance. ... (it) is therefore not to be considered a drain on public funds. (Submission from Hoffman Hospital Group to the Browne Commission Enquiry.
>
> (P)rivatisation of health services ... would lead to considerable savings in terms of demands made on

Table 1 : Three Components in Economic Organisation of Health Services and Available Options

Components of health service organisation and options within each component	Conventional categories and Institutional form usually taken
A. Methods of Financing:	
Public Methods of Financing:	
Taxes - General	Income, company, property taxes
- Sales tax, import/export duties	Sales tax, tariffs and duties
- Charging out costs to those who generate them	Motor vehicle licences and compulsory third party insurance
	Taxes on tobacco, alcohol
	Workmen's compensation contributions from employers
Deficit financing	Deficit financing and foreign loans
Foreign Aid grants (bilateral/multilateral)	Foreign Aid grants (bilateral/multilateral)
Lotteries and betting	Lotteries and betting
Public, Quasi-public or Private Financing Methods:	
Employer & employee contributions (other than general taxes)	Direct provision of, or payment for health services by employer
	Payroll taxes
	-National health insurance
	-Social security, compulsory health insurance
	-Private health insurance
	Charges related to generation of costs
	eg. workmen's compensation
Private Methods of Financing:	
Charitable contributions	Frequently from wealthy families, firms, religious groups
Private health insurance	Private health insurance
	Direct household expenditure
User charges	Direct household expenditures— for treatment and drugs etc.
	Co-payments — proportion of total costs, deductibles,
	excess above ceilings, for excluded benefits
B. Reinmbursement of Providers	
Fee-for-service	Private practice
	"Indirect " social security (eg as found commonly in Western Europe)
	Private health insurance
	Direct household expenditures
Capitation /pre-payment fees	Health maintenance organisations
	National Health Service "contract
	arrangements" with GPs (eg Britain)
	Community based/cooperative financing
	(eg Brigade level health care, China)
Salaried/budget allocation	Government provided health services
	"Direct" social security systems
	(eg as found commonly in Latin America)
	Employer provided health services
Others eg. bonus systems, merit award	
C. Patterns of Ownership	
Predominantly public owned health service (other sectors very small)	eg National Health Service (UK), small private sector, small or no quasi-public sector.
Multiple sectors, Many private providers as well as public and quasi-public sectors	Public sector as well as one or more social security schemes and/or employer providers and/or self employed practitioners
Community owned health services	Community financing [16]

the central coffers (Report on Privatisation and Deregulation of Health Care in S. A., 1986 — hereafter referred to as the Report on Privatisation.)

However, the private sector is not, at present, "self - perpetuating and independent of government finance." For, the public sector subsidises the private sector in numerous ways.

Tax concessions: Under corporate tax law, the contributions paid by employers are tax deductible, and the contributions paid by individuals are abatements under individual tax provisions. In 1982, medical schemes' income from contributions was approximately 54 per cent of total private health expenditure (26 per cent of total health expenditure) of which at least one-third is subsidised by the state, i.e. the real cost is 50 per cent more than what employers and employees pay. [17] This loss of tax r ue (at least R337 million in 1982), was equivalent to 1 er cent of total public sector health expenditure, and more than twice the total amount spent on preventive ser ices.

Subsidies For Medical Education: The major share of the costs of medical education is borne by the public sector. This is a form of 'human capital' investment by the state. When the doctor is employed in the public sector, it may be assumed that his/her salary undervalues his/her output by an amount equivalent to the return to the state on its investment. When a doctor is either self-employed or employed by another sector, the additional value accrues to him/her and to his/her patients. This value is an effective subsidy to those sectors from the public sector.

Estimates of the cost to the state of the undergraduate training of a doctor vary from R36, 000 [18] to R100, 000. [19] 937 doctors qualified in 1985, half of whom will eventually work in private practice. This is equivalent to a state subsidy of R47 million (2.4 per cent of public expenditure) to the private sector, excluding the costs of post-graduates' training.

Subsidised Use of Public Facilities: Publicly financed facilities are usually available to private sector patients (especially for sophisticated tertiary care), but also frequently for routine care under private doctors. Most patients requiring emergency admission are admitted to public hospitals regardless of their income and whether or not they are covered by medical aid. These patients are charged at less than the running costs of maintaining the beds (i.e. ward costs), let alone the full costs of investigation and treatment. In 1984/5, in the Cape, the average daily cost for an in-patient at a teaching hospital was R130.14, for which the maximum fee of R45.00 was charged. (In provincial non-teaching hospitals the costs and maximum fees were R55.45 and R36.00 respectively.) [20] Thus the government is subsidising the non-public sectors.

Other Forms of State Subsidisation: The government, as one of the largest employers' pays employer's contributions so that its own employees will have medical aid coverage, and be able to use the private sector providers. Many other forms of subsidy would be too complicated to measure — e.g. the costs of training nurses and other health workers, the cost of research, drug testing and control, and other parts of the health service infrastructure which benefit private sector, and public sector patients alike.

Thus it is not at all clear that the private sector does indeed release public resources for use on services for those who cannot afford private health care.

It is likely that the individual who uses the private sector providers costs the government more in subsidies than is spent by the government on individuals who depend on the publicly funded services. [21] The subsidy to the private sector therefore, distorts public sector resource allocation in favour of those who are already the most privileged. However, there is no theoretical reason why subsidisation of the private sector cannot be reduced.

The state could quite conceivably withdraw tax concesions; it could charge private patients the full cost for the use of public facilities; doctors who leave the public sector could be obliged to pay an additional tax on their earnings, etc. Withdrawing all subsidies may raise the costs of private health care so high that demand is transferred to the public sector. The costs of meeting this demand may therefore reduce the net savings to the state.

Nevertheless, the assumption that other sectors release public resources which can be directed to higher priority services, often ignores the many ways in which the public sector subsidises other sectors, and the distortive effects this has on public sector resource allocation.

Second Assumption: Only Private Sector Services Can Raise Funds from Private Sources.

The second assumption in the argument that privatisation increases total funding for health services, is that publicly owned services are financed from public sources of funds, and privately owned services, from private sources which would not otherwise come into the health sector. As the Report on Privatisation expressed it, "Privatisation seems to imply a shift towards health as a personal responsibility and feel and unlimited access to health care as a privilege."

Yet this assumption fails to separate, and distinguish between, private ownership of services and private sources of finance. Privatisation of ownership is only one way of getting private individuals to finance their own health care. For, user charges can be a method of financing public sector providers just as it is for the fee-for-service providers. Publicly owned services need not be financed entirely from taxation, but can draw on other methods of financing as well, e.g. social security, health insurance and user charges.[22]

Third Assumption: Political Pressure for Public Funding Will Not Decrease.

The third assumption is that the existence of a private sector would not inhibit or depress the amount raised by public methods of financing and allocated to health care. Yet, in the presence of other methods of financing from private sources, and alternative private providers, it is likely that the people with political influence (usually the relatively wealthy, urban dwellers with regular employment), will not be dependent on the publicly financed services. There is a strong chance, therefore, that they would not lobby either for increasing the tax effort or for allocating a greater proportion of public expenditure to the health services.

Thus privatisation has been seen as a way of offering urban, middle-class blacks access to racially integrated medical care of better quality than is available in the public sector. This has been motivated precisely by the belief that it defuses the political pressure from this articulate group to improve public health services for blacks in general, which would be extremely expensive. And as the Report on Privatisation concludes, "There is likely to be an overall saving to the taxpayer." Yet this may be one of the greatest dangers of privatisation, and may result in little increase in the total resources allocated to health care, and a decline in public sources of finance for the health services.

It is possible, though, that if a future democratic government were committed to providing the best public service the country could afford, that the existence of the private sector would not reduce the political pressure for raising public finances, and therefore total finances could be increased by permitting other sectors to operate and raise funds. Roemer's research in Latin America, for example, suggested that there was no decrease in the allocation of public funds to health services with the growth of the social security systems there. The overall level of resources available was indeed increased, and he argues that money that would otherwise have been spent on the costly and inefficient private health sector (if it had been spent on health at all) was channelled into the more efficient social security sector. At the same time, governments were able to devote larger proportions of their expenditure to deprived rural areas.[23]

The economic organisation of the health services should ensure that, for any given total expenditure, the health outcome is maximised. The concept of 'efficiency' encompasses both (1) financial efficiency and (2) economic efficiency.

Financial Efficiency

Financial efficiency is a measure of the proportion of total expenditure that is spent in the direct 'production' of health care. If system 'A' produces the same output of health care as system 'B' but at lower cost, then 'A' is more efficient, financially, than 'B'.

With respect to methods of financing, financial efficiency refers to the difference between the gross and net yields of a particular method of financing. This relates primarily to the cost of administering the collection and allocation of funds. Other measures sometimes considered are the difference between actual and hypothetical gross yields and reliability or stability of a source.

The protagonists of privatisation claim that public methods of financing are financially inefficient. For example, in its conclusion, the Report on Privatisation and Deregulation in SA claims that, with privatisation, "more funds would be available for the direct delivery function through a reduction in regulations, interventions and central decision-making".

Yet there seems to be little evidence to support this. The government spends 0.34 per cent of tax revenues on tax collection, and 0.9 per cent of public health expenditures administering financial allocations to the health services.[24] Most medical schemes, on the other hand, spend between 6 per cent and 10 per cent of their income from contributions on administration, i.e. calculating and collecting contributions and processing claims.[25] There are also numerous examples of overcharging by private hospitals, since it is difficult for medical schemes to check the bills and there is little incentive for patients to check them, even if they are informed enough to do so. This reduces the efficiency of this method of financing, since it results in more being spent with no increase in output.

This evidence is compatible with the findings of two recent international health care expenditure surveys. Commenting on them, Navarro concluded that western industrialised countries with the greatest government funding and administration of health services have the greatest population coverage and the lowest administrative costs.[26]

There are no estimates of the costs of collecting user charges either in the public or private sectors. However the relative costs will largely depend on whether the user charges are flat rates, or are related to the costs of providers (as with fee-for-service providers). This will therefore be covered in the next section (on the efficiency of different methods of remuneration).

(a) Private fee-for-service hospitals: Many of the arguments presented in the South African literature in favour of privatisation, are based on the belief that competitive providers motivated by profit and dependent on fee-for-service for their income, are financially more efficient than non-profit, government-owned services where facilities have fixed budgets. These arguments also reflect a faith in the power of the free market to prevent higher costs and excessive profits being passed on to the consumer in higher prices.

A criticism frequently made about the financial management of public sector hospitals is that "public hospitals in South Africa do not operate on a true costing system and

nobody actually knows what it costs ... to keep a patient." This criticism is valid. However, it does not follow from this that these hospitals are managed inefficiently, and the lack of cost data means that no accurate comparisons have been made. There is therefore no good evidence to suggest that private hospitals are more cost effective than public hospitals.

Indeed, one might expect the reverse. For, firstly, there can be little doubt that the flat rate fees charged by public sector facilities, even when applied on some sort of means tested basis, are cheaper to administer than the user charges in the fee-for-service sector. For, in the latter, the need to calculate charges for each item (drug, investigation, use of equipment etc.) for each patient individually, makes billing complicated and costly.[27]

Secondly, most of the hospitals which operate on a fee-for-service basis are profit making enterprises. As the director of one of the Rembrandt group of hospitals said, "We came onto the scene in 1983 purely for business reason — we didn't do it for charity. We see the medical services industry as an area of growth." [28] The profit obviously accounts for some of the difference between the gross expenditure on health in the private sector, and the net amount actually spent on activities which improve health.

At a fairly crude level of analysis, there is considerable evidence suggesting that fee-for-service hospitals are more expensive for less output. Comparisons are hazardous because one is not comparing like with like. For example, the costs per patient-day in public hospitals may include the costs of training personnel, of treatment, drugs, etc, but generally exclude capital expenditure, while for fee-for-service hospitals, ward costs exclude medicines and treatment, but include amortisation of capital expenditure. There is usually no training of medical staff in private hospitals. The quality of care and of the 'hotel' functions may differ. Furthermore, many of the most expensive treatments are available only or mainly in public hospitals (e.g. cardiac surgery, neonatal intensive care) because these are not covered by most medical schemes, or they are not profitable. The following comparisons must therefore be treated with due caution, though the order of difference seems so large that it is doubtful that the direction would be altered by the net effect of these biases.

In the Cape, the Groote Schuur teaching hospitals had an estimated daily average cost per unit of R108.37, and an average for all Cape provincial and aided hospitals of R63.43. In the Transvaal, in 1983/4, the median cost per patient day of 69 provincial and provincial-aided hospitals was R63.27. [29] Compared with this, fee-for-service hospitals are estimated to cost R100 per patient per day for ward costs alone (hotel and nursing services), before the costs of any doctors fees, theatre costs, investigations, drugs etc. are added. [30] On the other hand, in some private sector industrial hospitals, which are non-profit, with salaried health workers, and which do not have to compete with other providers (as employees are obliged to use the services provided), the average cost per patient day in 1984 was R30.61, inclusive of all drugs and treatment. [31]

Table 2 : Comparative Costs of Specific Curative Health Services in Public and Private Sectors 1984.

	Cost to Cape Provincial Administration	Cost to private patient at medical aid rates
GP Visit	R 10.00(a)	R 39.50(b)
Obstetric Confinement	R 567.00(c)	R 850.00(d)
Herniorraphy (5 day stay)	R420.00(e)	R 990.00(d)
Pneumonia (5 day stay)	R 420.00(e)	R 700.00(d)

Notes:

a. Cost per patient seen at Cape Peninsula Day Hospital includes investigation, minor procedures, day theatre cases, district nursing and medicines.

b. GP visit and average medical aid pharmaceutical cost of R30 per patient.

c Cost per confinement at Peninsula Maternity Hospital, including complicated obstertrical cases and neonatal ICU facilities.

d. Uncomplicated normal medical aid patient.

e. Cost to the Cape Provincial Administration of a 5 day stay in Victoria hospital (a non-teaching hospital).

(Source: Frankish J, Thomson E, Budlender D, Zwarenstein M, Dorrington R, Bradshaw D. *Privatisation of Health Services — Who Benefits?* Unpublished. 1986.)

A more comparable and accurate analysis of costs in the public and fee-for-service sectors has been made by Frankish et al (Table 2).

In the light of the above, it is interesting to note the findings of a recent study in the United States, which compared the differences in the economic performance of matched pairs of 'for-profit' and 'not-for-profit' hospitals. While there were no significant differences in patient-care costs, the total charges and net revenues per case were both significantly higher in the 'for-profit' hospitals due to higher administrative overhead costs. The author concluded that 'for-profit' hospitals generated higher profits through more aggressive pricing practices rather than higher operating efficiencies. [32]

The imperfections of the market, in the case of health care, have been frequently discussed in the literature [33] and cannot be reviewed here. It may be concluded, however, that the evidence available suggests that the profit motive, and the competition of multiple fee-for-service private hospitals are no guarantee of greater financial efficiency. Indeed, such an economic structure is probably less efficient.

(b) *Effects of Methods of Remuneration on Efficient Use of Personnel Resources:* Doctors in SA have jealously guarded their monopoly over the right to diagnose and treat, and 'primary health care nurses' have only been allowed to perform a limited range of tasks in certain prescribed circumstances. There is adequate evidence from all over the world that, in both developing and developed countries, other health workers can perform many of these functions at lower training and salary costs. Yet South Africa's present inefficient system will not change as long as doctors earn more for seeing patients themselves, as occurs in a fee-for-service system. If, for example, doctors were paid a capitation fee, then it would be in their economic interests to employ cheaper health workers to perform the tasks for which they are competent, so that their own more expensive skills could be used more efficiently, while covering a much larger population.

Effect on Financial Efficiency of a Multi-sector Pattern of Ownership.

(a) *Wage inflation:* The competition between sectors for fixed resources forces up wages in both the public and private sectors. Comparing salaries of professionals in the public sector in 1984, the median salary (before tax) of male doctors was 26 per cent higher than engineers, 39 per cent higher than lawyers, but only 4.5 per cent less than doctors in the private sector. [34] As one private hospital managing director said, "We just take a lead from the government hospitals. When they increase their rates we simply add a bit more on to get the staff." [35] This is unrelated to productivity, and hence is purely inflationary and is financially inefficient.

(b) *Duplication and Economies of Scale:* In 1974, the de Villiers Commission found that there was a lack of planning, especially between provincial and private hospitals — an excess of beds had been provided in certain urban areas, resulting in too low a rate of occupancy in provincial hospitals as well as private hospitals. [36] But this is not merely the result of poor coordination. It is the inevitable consequence of access to different providers being restricted to different groups in the population (the rich and the poor) when these groups overlap geographically. Thus there will be many areas where both public and private facilities overlap merely because they are not open to all the people who live near them. If this results in the failure to achieve economies of scale, then average costs are high, and the arrangement is financially inefficient.

Economic Efficiency

Economic efficiency, as opposed to financial efficiency, is concerned with the allocation of resources in socially optimal ways. The reality of finite resources means that more of health care entails less of something else, and within the health sector, more of one type of health care means less of another. Optimal economic efficiency occurs when the marginal rand produces equal benefit, no matter where in the economy it is spent. In a free market, the price mechanism may equilibrate supply and demand in a way that reflects individuals' relative evaluation of alternative combinations of resource allocation. However, in the health care market, the price mechanism fails to achieve economic efficiency for several reasons: the presence of monopolistic providers (e.g. doctors); consumers are not well-informed and have difficulty choosing between alternatives; providers influence consumption more than consumers; there are significant externalities such that the social benefits exceed the sum of the individual benefits (and therefore willingness to pay); and unequal income distribution results in monetary prices reflecting different marginal utilities at different income levels. [37]

Consequently, other mechanisms are needed (some of which may also use prices as signals to providers and consumers) to promote efficient resource allocation. Broadly speaking, these mechanisms act either on the providers to influence the supply of health services, or on the consumers, to influence the demand for health care.

The efficient allocation of resources therefore, depends inter alia on: (1) The ability to control allocation on the supply side — determined largely by the pattern of ownership of the services. (2) The ability to control demand for health services, i.e. to limit demand for each kind of service to levels that are socially optimal — dependent on the methods of financing and remuneration.

There can be little doubt about the economic inefficiency of resource allocation in a country where heart transplants are being performed while the vast majority of the population suffers from vaccine preventable diseases. This failure to allocate resources to where they will achieve the greatest health improvements for the maximum number of people, occurs because the economic agent, the decision maker, is split into parts with independent allocation systems. The result is that the benefits and opportunity costs of a given allocation are borne by different parts of the system. Put another way, even when the marginal rand spent by different parts of the system produces highly unequal benefits, no transfer of resources occurs between the separate parts of the system, in favour of those sectors where they could produce a greater marginal benefit.

The present system prevents the optimal allocation of resources in two ways. The first is the racial and geographic fragmentation of the public health service and the division of control over total health care spending between many sectors (government, medical schemes, employers, private individuals). The other is, of course, the control of public health services, by an undemocratic minority government. For such a government, the present policy may be 'rational' in the sense that it serves the interests of that government. Thus even if there was a single authority controlling all health resource allocation,

in the absence of a democratic government, health policy would be unlikely to benefit the maximum number of people.

Yet, assuming that in the future there is adequate democratic control over public health expenditure, if private expenditure is significant, it will continue to produce inefficiencies since private individuals do not suffer the opportunity costs of withdrawing trained personnel and technology from the public sector. The effects on the public sector could be minimised, though, by removing any subsidy to the private sector. Then, if private individuals were willing to carry the full cost of, say, haemodialysis, public sector resources would not be diverted and the optimal allocation of public expenditure need not be reduced (although the economic efficiency of *total* expenditure would still be suboptimal).

The determinants of demand for health services are multiple and complex. Financial incentives are clearly only one group of determinants. Furthermore, it is difficult to say what the appropriate level of provision for any particular service is. However, in terms of economic efficiency, the quantity provided is optimal when it costs what society is willing to spend on it, i.e. the value society places on it relative to other possible uses of those resources.

When the economic organisation of the health services does not have adequate mechanisms for limiting demand to the level for which resources have been allocated, demand will exceed its optimal level, drawing in more resources and resulting in economically inefficient resource allocation. This also means that cost escalation cannot be controlled.

(a) Economic Efficiency and Methods of Financing: Third party methods of payment frequently result in economic inefficiencies and cost escalation. If individuals had to pay the true marginal costs of medical care, they would allocate their resources according to how they valued each, which would ideally reflect the relative cost-benefit of each. A collection of individuals, in the form say, of the state (ministry of health), or an insurance group, should allocate their collective resources the same way. However, having paid their insurance contributions, individuals who no longer have to sacrifice more in the short term for demanding more expensive curative care, will demand more than the value of that care to them (the problem of 'moral hazard'). Assuming, for this example, that the provider faced no financial incentives either to provide or withold treatment,(s)he will attempt to do what is best for the patient personally. To serve the patient's interests well,(s)he will administer additional care as long as there is some net benefit to the patient.

Yet this may be excessive from society's point of view since the same resources could have achieved greater overall welfare had they been used for some other purpose. In the long term, costs will escalate, with aggravated distortions and growing economic inefficiency.

(b) Economic Efficiency and Methods of Remuneration —Problem of Perverse Incentives: In the example above, it was assumed that the provider was interested only in what was best for the patient. However, given firstly, that the provider is the main determinant of demand for investigation and treatment, and for secondary and tertiary care, and secondly, that the patient can afford almost any fees either personally or through risk sharing arrangements, the fee-for-service system offers financial incentives to the provider to perform more investigations and treatment than are necessary or justifiable. This is the problem of "perverse incentives."[38] In Brazil, for example, doctors and hospitals receive the highest fees from private patients, slightly lower fees for patients on social security, and the lowest for indigent patients (paid by the government). The rates of caesarian section in primiparous women in 1981 were 75 per cent in private patients, 40 per cent in insured patients and less than 25 per cent in indigent patients.[39]

Usually the interests of the income maximising practitioner will not be in conflict with those of the patient — the marginal investigation may indeed increase the certainty of diagnosis. Furthermore, other non-financial incentives such as status, career advancement, medical ethical principles and regard by peers may protect the patient's interests. However, all these incentives work in the same direction as the financial incentives, encouraging the doctor to 'do more' rather than less, with little regard to the economic costs to society. Thus the system of fee-for-service remuneration aggravates the problem of efficient resource allocation and results in the dramatic cost escalation.

By contrast, the incentive effects of remuneration by salaries and capitation fees do not have the 'perverse' effects that occur with fee-for-service, with its consequences for cost escalation and economic efficiency. In prepaid (capitation) group practices the providers undertake to cover part or all the costs of treatment that a patient may require during the next year (or other period of time). This creates financial incentives not only to keep patients healthy in the first place, but also to limit unnecessary or excessively expensive tests, drugs, referrals etc. Saward and Fleming, for example, have shown that prepaid group practices can be more cost-effective than fee-for-service systems, largely because of lower hospitalisation rates.[40]

In S.A, as in most other countries, per capita expenditure on health care has escalated in real terms. One source (in the Report on Privatisation) estimates that real per capita expenditure by the state increased by 13.5 percent from 1975/6 to 1984/5 (i.e. 1.4 per cent annually, compounded). On the other hand, average Medical Aid premiums (which approximate per capita expenditure by medical schemes) have increased 500 per cent from 1975 to 1986 compared with an inflation rate of 387 per cent over the same period

(a real annual increase of 2.3 per cent compounded), i.e. more than 1.6 times the per capita rate of increase of public expenditure. [41]

Another source puts the increase in total (public and private) real expenditure on health (not per capita) at 26.5 per cent from 1978 to 1982 (or about 6 per cent annually compounded). Over the same period medical schemes' total real expenditure increased by 31.3 per cent (or 7 per cent annually compounded). Some of the factors that have contributed to cost escalation over the decade have been demographic changes e.g. aging white population, urbanisation of blacks, increasing income and sophistication of patients, increased coverage by medical aids (membership has been increasing by about 20 per cent in five years), increased provision of services, increasing costs of high technology equipment combined with a falling exchange rate, recession and poverty. All these trends are likely to continue. The economic organisation of health services ought to be able to contain costs at appropriate levels. Yet, there is evidence that in both the private sector and public sectors, the structure aggravates cost escalation and does not provide mechanisms for its control.

An increase in expenditure on health care is not in itself a bad thing, especially since the proportion of the GNP devoted to health care is relatively low (4.9 per cent), compared with most industrialised countries. Yet the following quotes indicate that, in the private sector at least, the cost escalation is due to the inability to limit demand to socially optimal levels i.e. to growing economic inefficiency.

In 1985, John Erntzen, chairman of the Representative Association of Medical Aid Schemes of S.A. (RAMS), said that as a result of increased claims: medical aid schemes throughout the country are on the brink of collapse ... (T)here is evidence that doctors are offering more services, often unnecessary, to make a living. ... RAMS has also found that doctors charge more and offer less services at any given consultation. ... (T)he man-in-the-street also insisted on a lot of treatment because he felt he was entitled to it because of his medical aid membership. [42]

He also claimed that, while medical tariffs in 1984 were an average of 4.4 per cent higher than in 1983: (y)et we have found that our claims costs for 1984 rose much higher than this: up 19 per cent on 1983 for general practitioners and 25 per cent for specialists. This can only suggest that more services are being performed (per beneficiary). Those doctors who rely on medical schemes for their income see our members on average 25 per cent more than those doctors contracted out." (Tony Leveton, executive chairman of Affiliated Medical Administrators [43].

And, in the Report to the Department of Health on Privatisation and Deregulation in SA, it is claimed that the "disproportionate increase (in private medical expenditure) can most likely be ascribed to an overuse of health care facilities in the private sector due to the present structure of Medical Aid Schemes".

These are exactly the obstacles to economic efficiency that are created by the inability to contain excess demand due to the moral hazard problem of third party methods of payment, and the perverse incentives effect when suppliers who influence demand are reimbursed on a fee-for-service basis.

This report to the department of health recognised that "the present triangular arrangement (consumer-provider-funder) is highly inflationary" and that, in such a system, "with state subsidy to individuals, the results could be disastrous." Yet its answer was that, " to overcome this, prepaid cover for health care should be market-oriented," so that people could attain the kind ofcover they require. But this is a *non sequitur*. For, no amount of market orientation will alter the inflationary triangular arrangement. The report goes on to say that the members of the four working groups that produced the report could reach no agreement because of strong vested intreests", and that this "requires much further detailed study once the principle has been accepted." (One might have thought that such a study should precede acceptance!)

Thus, on the one hand, they are unable to accept the logic of their own arguments because the conclusions would conflict with"strong vested interests". On the other hand, since they refuse to question their assumptions about the efficiency of private sector health care, any observed inefficiencies in the present system are regarded as the indications that further privatisation is required. As we have seen, the real problems are the fee-for-service method of remuneration and the dependency on health insurance as a method of finance.

These are not the only obstacles to limiting demand to socially optimal levels. Any mechanism that lowers fees below their marginal cost may result in `excess' demand. And, as was suggested above, even when there are no perverse incentives (such as with salaried doctors), supplier induced demand, and hence costs, are difficult to control. These latter problems occur in the present structure of the public sector, since the doctor does not have to carry the costs of the quantity of care (s)he provides, and the opportunity costs of such care frequently exceed the marginal benefits. However, in the public sector, where total expenditure is constrained by a predetermined budget, suitable management mechanisms could be developed to control the supply of services and thus control costs.

Any changes in the economic organisation of health services designed to meet the objective of greater economic efficiency, must clearly move *away* from these methods of financing and remuneration by introducing selective user charges; by reinbursing providers on a capitation fee or salary basis; and by making providers bear some of the cost of the demand they induce. In the public sector, manage-

ment systems will be required to ensure that resources are directed towards those communities and types of health care that produce the highest marginal benefit.

11. Zschock D T. *Health Care Financing in Developing Countries,* APHA International Health Programs Monograph Series No. 1, 1979 pp 19-33. Although both Zschock and WHO call these 'sources', it is recognised that "for different purposes it may be useful to define sources in different ways". (World Health Organisation. *Financing Health Services. Report, of WHO study group. Technical Report Series No. 625,* Geneva: WHO, 1978, p 36.) For example, the above taxonomy considers tax revenue paid by individuals and companies a public source. If we were concerned more, say, with examining equity implications, we might identify the sources as those who paid the taxes. This taxonomy is useful because most of the concern has been about how to increase the resources available for health services, and is therefore about the most appropriate institutional arrangements for channelling finances.

16. Community financing and self-help does not fit easily into any system of classification because it encompasses so diverse a range of options of health service organisation, e.g. contributions in kind, such as labour, materials, agricultural produce; user charges for drugs and services; household or communal contributions to pay the wages of a health worker as part of a risk sharing arrangement. (Stinson W. *Community financing of primary health care.* Washington DC: Primary Health Care Issues. Series 1 no.4. American Public Health Association. 1982.) The main virtue of considering community financing as an entity is that it draws attention to the use of non-monetary resources, local sources of finance that are often overlooked, and other factors that may be important for the success of projects, such as community participation. Although it has recently become the focus of much attention as a means of tapping resources in poor communities for health and health related services, the particular strategies considered can be fitted into one of the methods in the left hand column of the table and can be similarly analysed. Some forms of community financing may be considered to be unique in their pattern of ownership — viz. where services are owned by the community, as opposed to private or public (state) ownership.
17. For every R1 contributed, 50c is paid by employers, most of whom are companies. The company tax rate is 50 per cent, thus the company effectively pays only 25c and the government pays the other 25c (through loss of tax revenue). The employee pays the other 50c. The lowest rate of individual taxation is 16 per cent (the highest rate on the marginal Rand is 50 per cent). Even if all employees are assumed to be on the lowest rate, the effective government subsidy is: 16percent X 50c = 8c. Therefore the total minimum subsidy is: 25 + 8 = 33c in the rand.

Fee for service and the right of practice of private practitioners in provincial hospitals. *In Hospital and Nursing Yearbook for Southern Africa,* 1985. Cape Town: H. Engelhardt and Co., 1985, p41. Note: Since 1984, fees at provincial hospitals have increased enormously, and in some provinces, patients covered by medical aid are now charged at the standard rates that medical aids are prepared to pay.
21. The total value of these government subsidies, divided by the number of people who benefit from them (approximately 20 per cent of the population who use the private sector providers), is likely to be more than per capita public sector health expenditure. The tax concessions alone, which equal at least 17 per cent of the public health budget, benefit only about 16 per cent of the population (the proportion covered by medical schemes). If the whole public sector health budget were distributed evenly over the whole population, the per capita expenditure would be less than the amount of the tax subsidy to private sector users.
22. The Chinese system comes fairly close to this arrangement. At secondary and tertiary levels of care, there is only one sector providing care and this is charged for. The methods of financing used to pay these charges depend on whether the patient is a government employee, a commune or brigade worker, a factory worker, a dependant of a worker, or not covered by any risk sharing arrangement in which case (s)he must carry the full cost privately. other than what was already being written about. We were in no competition with fraternal journals which were focussing on these issues. And most of the ongoing debate on the three issues, whether in the mainstream or in the alternative press were themselves major contributions to the radical critique of health. There was another perhaps more important reason. For all of us on the collective the ***RJH*** was the second or third area of activity. That is all of us at different levels with different groups were already very much involved with these issues. The other forums, such as the **medico friend circle, the All India Drug Action Network, The Health Services Association and the West Bengal Drug Action Forum, Kishore Bharati,** women's groups and others, were putting in a tremendous effort to generate a public debate on critical problems in these areas. By tacit consent we decided to put our energies into these for a rather than in brin out substantial material in the ***RJH***.

What now? Do we still feel that the journal can fulfill a need? Have we contributed to the development of a marxist debate on health care? Certainly things have changed much since we began. For one thing the last four years have seen an upswing in the interest in and awareness of health issues. Interestingly the three issues we mentioned above have been both a cause and consequence of the changing situation. During this period we have also seen a large number of health periodicals, some occasional, some regular, emerge. Also, publications encompassing a broader canvass of social analyses have begun to devote more space to health issues.

We do not attempt here to answer these questions. Because we really have no means of evaluating the ***RJH*** qualitatively. We invite you, our readers new and old, to give us your feedback. Because after all the whole point in starting this journal was so that it could provide a forum for participating in the evolution of a radical, marxist critique of health. In the meanwhile we will continue to do our bit as best as we can.

So here comes a fifth year of ***RJH!***

Health Care, Health Policy and Underdevelopment in India

ravi duggal

SINCE independence health policy making and the design of health programmes (like all other development programmes) have been guided by programmes of imperialism. As a result the Indian peripheral population has been denied state-sponsored health care services (that exist theoretically) and have instead had to depend on the vagaries of the market forces in which operates the overwhelming private health sector that has virtual monopoly of curative health services, being supported to the hilt by the multinational pharmaceutical industry. Privatisation, high technology, population control, low-cost models, aid and the consequent dependency are the means imperialism uses to shape our health policy and programmes.

THE underdevelopment of health is not an original state, but an active process generated by imperialist exploitation. Thus the nature of the third world health problems and the obstacles to their solution are to be found primarily in the structure of the economic relations historically created between the capitalist powers and their satellites. This is reinforced by the economic and social relationships created by imperialism within particular underdeveloped countries. [L Doyal and I Pennel. *EPW* August 1977]

The links of underdevelopment with imperialism are today well established. The world systems approach [Baran, 1975; Frank, 1967, Amin, 1974; Wallerstein, 1976] that critiques the developmentalist paradigm of liberal political economy has also looked at the health sector, then it moves on to discuss the underdevelopment of the health sector in India establishing the linkages with imperialism based on an analysis of health and population control policy.

Modern medicine got established in the developed world only in the last quarter of the nineteenth century. And now for over a century it has prospered under capitalism and has spread globally under imperialism expropriating the health of the people. In developed countries sanitary reforms and other public health measures had provided the foundation on which modern clinical medicine could grow and flourish. This did not happen in what are today's underdeveloped countries because the latter were colonies of imperial powers. In underdeveloped (colonial) countries modern medicine developed as an enclave sector and therfore, though early in introduction, modern medicine catered to a very small proportion of the population.

The phenomenal growth of modern medicine under capitalism in the last one hundred years and its expansion under imperialism had no doubt revolutionised medicine. But in its rushed growth to find a pill for every ill the medical-industrial complex, under the auspices of monopoly capital and imperialism has not only become an expropriator of health but also global expropriator of surplus through a network of large multinational corporations. Good health is not only a question of availability and accessibility of modern medical care but is also related to the basic question of the right and access to a comfortable, human standard of life.

Today the difference we see between the developed countries of the west and the undeveloped countries of Asia, Africa and Latin America is the gap that imperialism has created. The question is not one of lack of resources in the peripheral (underdeveloped) countries but that of expropriation of their resources by the centre (developed) countries. The world product today (far below level as which human beings can produce with the present level of productive forces) works out to over US $ 3500 per capita per annum. If equitably distributed this is sufficient to support a comfortable life-style for the entire global population. However in the present world the underdeveloped countries, which have over 3/4ths of the world's population, get only 1/5th of the share of the world's product [World Bank, 1984]. The situation in 1800, for instance was a little different. The same population of underdeveloped countries had 44 percent of the share of world output. Since 1800 the gap has widened because of the expropriation of surplus of the underdeveloped countries by developed ones, earlier through colonisation and now through imperialism. And this gap today is widening further because of the stepped up process of privatisation all over the world. Thus under capitalism and imperialism development alone is not possible-development is necessarily constructed on the foundation of underdevelopment. The growing of such a development (increasingly for fewer people) also means a growth of underdevelopment (increasingly for more people). [see Navarro, 1976] health sector.

A futher point to be noted with regard to the health sector is that it has historically belonged to the category referred to in western economics as the welfare or social sector. The argument is that a healthy population is essential for higher productivity. But under capitalism the production sector is unwilling to bear the burden of maintaining the health of the population, therefore this function is transferred to the state. The state collects taxes and makes provision for health care services either through its own delivery system or through subsidies or support of the private health sector. But with the strengthening of monopoly capital, contradictions of capitalism become completely bare and it seeks the support of the

state, the latter tripping into a fiscal crisis. The direct consequence is a demand by capitalism for a cut in social expenditures (health, education, welfare etc). However, at the same time monopoly capital is well prepared to take on social expenditures because new techonological developments have rendered this sector profitable. It is not that there were no profits in the health sector earlier-the pharmaceutical industry, private pracitioners, medical equipment manufacturers etc were grossing large surpluses. Only now, because of the new medical technology, large scale corporatisation of health services has become possible.

This development in the health sector is not restricted to the developed world. It has diffused very rapidly in the underdeveloped world further advancing (sic) the underdevelopment of health in these countries. The developed and the peripheral mass has less and less of basic health care. On the contrary, imperialism pushes 'new' low-cost, self-care models for the periphery. "In the health sector, we find substantial cuts in government health expenditures with privatisation and commodification of medical services, accompanied by the ever-present ideology of self-sufficiency and self-care brought to those peripheral countries by transmission belts of dominant core ideologies, such as the international agencies of aid". [Navarro, 1984].

Underdevelopment of Health in India

In India the growth of the health sector has followed the enclave pattern of development. Public health in India was completely ignored. Unlike Europe, India and most of the third world missed the opportunity of implementing sanitary reforms because they were colonised [for details see Ramasubban, 1985]. Even until today, because of the nature of capitalist medicine and imperialism, this simple and basic change has not been possible in underdeveloped countries—the entire focus of modern medicine is centred around the clinic and the only beneficiaries of this are the providers and monopoly capital. The recent cholera and gastro deaths in Delhi and other parts of India shows how underdeveloped public health in India is and it also proves the enclave sector pattern of development.

The genesis of an institutionalised health care delivery system in India began with the consolidation of British colonial rule. The motive of the imperial government for providing such modern and sophisticated medical care was not to improve health care of the general Indian community but as a concern for the health of its own armed forces and civilian administration. This very enclave sector introduction of modern medicine in India became the basis of its growth in the country. This pattern continues even today. Upto the end of the war modern medicine in India was not introduced to the periphery at all. It was only available to the rich Indians and civil servants, besides the Britishers and the Indian Army. With the advent of provincial government after the Government of India Act 1919, some semblance of a medical care network evolved. By 1941 India had 7441 hospitals and dispensaries (2150 hospitals). For rural areas there was one unit (hospital and / or dispensary) per 45,966 population and for the urban areas one unit per 16,913 population. (only 7.6 per cent of all these units were in the private sector) [Government of India, 1946]. Anyway, these facilities were too meagre to be of any significance, especially considering the fact that they largely catered to a select population.

Compared to any significant health care delivery system in the developed world the facilities and investment in India were miniscule and of little consequence for the health of its population. For instance, before the start of the second world war India had a bed/population ratio of 0.24 beds for 1000 population with a state expenditure of about 16 annas per capital only (5 per cent of Government expenditure), compared to Britain and USA which had bed/population ratios of 7.14 and 10.48 beds per 1000 population and a state health expenditure of Rs.54-8 annas 12 pies and Rs.51 -6-0 per capita (20.4 per cent and 13.8 of government expenditure), respectively [Government of India, 1946]. The fact is that Britain's and USA's state health expenditure was equivalent to India's national income and their health care even worse today. In 1984 health expenditure in the USA was $ 15.80 per capita out of which state expenditure accounted for 41 per cent (Levit et al,1985). By comparison in the same year health expenditure in India was only Rs.50 per capita. State private expenditure in 1984 is estimated at Rs.47 per capita by the CSO [GOI, 1988] but is more likely around Rs. 190 per capita [Duggal, 1986]. Even taking the latter estimate of private health expenditure in India, the USA spends 66 times more on health than India. Futher, the US health expenditure alone in 1984 was eight times that of India's national income (state health expenditure alone of the USA was 3 $^1/_2$ times India's GNP).

In India the Bhore Committee Report had provided the first insight into dimensions needed for a comprehensive health care system in India. It was a plan that was almost equivalent to Britains own national health service but having features closer to the Russian model because of Dr. Sigerist's and Prof.Ogenov's influence [GOI, 1946]. The committee stressed that suitable housing, sanitation and safe drinking water were primary conditions for good health was not to be equated with health services or illness care. The beneficiary was identified clearly as the tiller of the soil and the committee drew pointed attention to his plight. Specific groups such as women and children and industrial workers, were also paid special attention." [Giridhar et.al.,1985].

However, after independence the Bhore Committee Report remained unimplemented. The main reason for this, as also for the poor performance of other social

sectors, was the role of the Bombay plan (also known as Tata-Birla Plan) in shaping India's economic policy. Briefly, the Bombay Plan directed the nation's economic policy to serve the needs of private capital by making the state invest in heavy economic infrastructure, under the cover that such participation by the state in economic production would evolve a socialist society. That was as far as Nehru's socialism went and the private sector got state subsidised capital goods and services sector (steel, minerals, transportation, communmication, finance capital etc.) from which to reap benefits. It is clear that state investment has historically dominated in areas which helps the growth of private capital.

In the health sector the government let private practice of medicine flourish. For instance the government subsidised significantly the growth of private medical practice by training medical personnel from tax-payer funds and by providing bulk drugs at very low prices to private formulation units. However, the government took the entire responsibility of public health largely preventive and promotive programmes with curative services (the primary need of the population in terms of demand) taking a back-seat.

Investment in Health Sector

As mentioned earlier, at independence the investment in the health sector was marginal. Hospitals, dispensaries, health centres, health personnel and pharmaceutical production were abysmally low to have any impact on the health of the population, especially the poor masses. Between independence and today the growth of the state health sector has not kept pace with the needs of its population and quality.

Between the beginning of the first plan and 1986 the number of hospitals have increased from 1,694 (1,17,000 beds) to 7,474 (5,35,735 beds) but in terms of availability to the population the situation has not very siginificantly improved. Thus in 1951 one hospital served 1,34,001 population (3,085 population per bed) and in 1986, 1,003,48 population (1,400 population per bed). The situation gets worse when we look at the rural - urban differentials. For the earlier years this figure is not available but even in 1986 only 21 per cent of the hospitals (and 12 per cent of the beds) were located in rural areas, one rural hospital serving 3,49,394 rural population, and one rural bed serving 8,135 rural population. In comparison to this in the same year one urban hospital served 34,281 urban population and one urban bed served 432 persons in the urban areas. In 1956, 24 per cent of all beds were in rural areas but in 1986 this figure had declined to 12 per cent (GOI-CBHI, respective years). Further when we consider access factors like morbidity rates, sanitary conditions, malnourisment etc, the rural health sector investment appears to be only a marginalised investment. (See Table 1).

It also appears that compared to the growth of the private health sector the growth of the state health sector is very slow. For instance in 1974, 16 per cent of all hospitals were in the private sector (16.2 per cent beds) but within a decade in 1984 private hospitals had grown to 42.3 per cent of all hospitals (26.7 per cent) (Ibid). This means that availability of health care for the poor classes, who constitute more than 3/4th of the population, is becoming more and more expensive as they have to increasingly rely on market forces.

The urban population, besides having the cream of the state and private health services also have access to relatively good and well organised local-body sponsored health services, and the organised sector working class in addition has the benefit of having either health insurance [ESIS, CGHS] or reimburesement of costs (by employer) or even special health care facilities by railways, mines, defence, public sector undertakings, corporate health facilities).

To check this imbalance a network of primary health centres have been established to cater to the needs of the rural population. Between 1956 and 1986 the ratio of population served by one PHC has changed from 5,51,724 to 88276 but no siginificant impact on the health of the population is perceptible. The problem with this is that PHCs are different from hospitals and dispensaries. People's need and demand is for curative services (i.e. hospitals and dispensaries), rather than public health and family welfare. On an average only 1/5th of PHC funds and time of the staff are spent on curative services when over 90 per cent of those who visit the PHC seek curative care. When curative care supply in such institutions increases, such as in case of upgraded PHCs, its utilisation by the population also increases. Similarly a good PHC doctor (in terms of providing curative care) increases the patient-load of the PHC substantially.

Drug production is one area (the other being the production of doctors) in which considerable success has been achieved and the targets surpassed. The reason is simple that profitability is high and an effecient (even though largely irrational) pharmaceutical industry is the lifeline of private practice of medicine and vice versa. Pharmaceutical formulation production (including net of import/export) has increased from Rs.51 crore in 1956 to Rs.1993 crore in 1983 [FRCH, 1987]. In terms of population served, this means drug availability of Rs. 1.30 per capita in 1956 and Rs.27.68 per capita in 1983.

But the most important segment of the health sector in India is the private medical practitioner. Today there are over 700,000 medical practitioners (including institutionally and non-institutionally qualified and non-qualified from all systems of medicines); out of these 36 percent (250,000) are allopaths. Besides this there are about 800,000 paramedics, pharamacists, nurses, various medical teachnicians etc. Of all qualified allopathic

practitioners only 28 per cent are located in rural areas and out of these 40 per cent work in the government's rural health institutions. Of all non-allopathic (qualified as well as others) practitioners. 56 per cent work in rural areas; and from among these only 2 per cent work in the state health sector 6 per cent of qualified non-allopaths) and of course, most of them practise allopathy. So here again we see that rural-urban differentials are very marked. And finally what is the proportion of medical professionals working as private practitioners? Of the qualified allopaths about 172,000 (or 69 per cent) are in private practice. And of all the non-allopathic (qualified and not qualified) practitioners 90 per cent of 400,000 work as private practitioners. This means that about 5,72,000 practitioners (one per 1300 population) of all sorts constitute the largest chunk of the health sector, [extrapolated from Census -1984; GOI, 1986].

This overview of health infrastructure development and investment in India clearly shows that the pattern of growth of the health sector in India has only contributed to its underdevelopment. The three high growth areas of medical education, pharmaceuticals and private practice have only helped imperialism and monopoly capital. Development of health care service has been concentrated in the enclave sector benefitting largely the urban-enterpreneurial economy. Health care services, like all other sectors of the economy, in the periphery are backward and what little exists is both poor quality and of difficult access.

There are various issues health and non-health, involved in this debate.In this article the discussion is limited to the nexus between imperialism and the health and population control policy in India and how they perpetuate underdevelopment.

Health Policy and Imperialism

In the colonial period health policy was unabashedly in favour of the enclave sector. The periphery existed only for expropriation, not deserving even lip sympathy. However, a few years prior to Independence both the Government of India and the Indian National Congress decided that the health of the periphery needed attention. The now famous Bhore Committee and the National Planning Committee's reports on the health situation in India and what could be done about it appeared on the eve of independence. Both these reports clearly favoured the establishment of a broad based integrated national health system that would be equally accessible to the entire population, irrespective of their ability to pay.

The Bhore Committee report used the Flexner Report of the USA as its basis in chalking out the plan for health care services for India but the influence of both the British National Health Services that was then emerging and the Russian model are clearly perceptible. However, it is evident that the Bhore Committee Report was clearly designed within the framework of welfare economics. It is a different matter that most of the recommendations of the report were rejected by the Indian state because the shrewd Indian bourgeoisie preferred a system of health care services where health care and medicine would be commodities (for instance the then prevailing Indian Medical Service that could have become the foundation of a national health service, was truncated and finally dissolved). The state was given the responsibility of public health and health care services for the periphery. The state was also made to provide the infrastructure medical education and research, bulk drugs, tax rebates and subsidies. Private medical practice developed as the core of the health sector in India initially strengthening the enclave sector, then gradually spreading into the periphery as opportunities for expropriation of surplus by providing health care increased due to the expansion of the socio-economic infrastructure. It must be noted that this pattern of development of the health sector was in keeping with the general economic policy of capitalism. And Indian capitalism had clear links with imperialism. Thus the health policy of India cannot be seen as divorced from the economic and industrial policy of the country. In India until recently there was no formal health policy statement. The policy part and parcel of the planning process (and various committees appointed from time to time) which provided most of the inputs for the formulation of health programme designs. However what programmes were to receive priority was decided by imperialism.

In the early years after independence the Indian state was engrossed in helping and supporting the process of accumulation of capital in the private sector through large scale investments in capital goods industry, infrastructure and financial services. Social sectors like health and education were low priority areas. Industrial growth was the keyword. But by the end of the fifties imperialism had convinced the Indian state and the bourgeoisie that if the periphery was left out of the development process then not only surplus expropriation but the existence of capitalism itself would be threatened. Imperialism did not want another Cuba or China. Earlier the US patented CDP had failed. Thus the Green Revolution and subsequently other rural development programmes came to India through assistance from the US Technical Mission and Ford and Rockefeller Foundations. Along with this came support for health programmes also. The aid that came to India was not only financial and technical but also political and ideological. The entire policy framework, programme designs and foci, financial commitments etc. were decided by the imperialist agencies. For instance, during the fifties malaria, which constituted, an international threat, was the main focus of our health care delivery system an overwhelming majority of the health budget going into spraying out the mosquito menace. This priority was dictated largely by US imperialism - 78 per

cent of the US (health) technical assistance and 68 per cent of PL 480 grants went to malaria control and eradication [USIAD, 1976]. Similarly in later years small-pox eradication assumed importance. This time 57 per cent of all WHO assistance to India between 1973-76 went to small-pox eradication [WHO, respective years].

In the fifties and sixties the entire focus of the health sector in India was to manage epidemics. The health infrastructure remained grossly inadequate, catering largely to the enclave sector (see Appendix 1).

Another area of imperialist influence has been medical education and research. The entire curriculum of medical schools in India is oriented to serve western capitalism. Trained medical graduates, who have studied in public financed medical schools have migrated to western capitalist countries en masse, the latter gaining cheaply (for them) trained medical manpower. Imperialism directly perpetuates this form of medical education and migration centres of medical excellence in India (AIIMS, PGIMR etc.) have been funded by imperialist agencies. For instance between 1950 and 1974, 98.7 per cent of all health sector assistance by the Rockefeller Foundation to India went to medical education and research [Rockefeller Foundation, respective years].

In the early sixties, alongwith the great push given to the Green Revolution imperialism was preparing the ground for a fundamental change in India's health policy. The epidemics that were being controlled were bringing down the death rate rapidly. The consequence was a sudden spurt in population growth. India already had an official population programme but in the Mahalanobis scheme of things population growth was not a priority factor in planning. For imperialism the high growth of population (compared to their own declining growth) in India and rest of the underdeveloped world was a major threat. The initial beginnings in guiding this policy change in underdeveloped countries was routed through private foundations of American capitalism [for details see Mass, 1976]. In India, for instance 84 per cent of all Ford Foundation health sector aid between 1955 and 1979 went to population programmes and reproductive biology [Ford Foundation, respective years].

In the first two plan periods the family planning programme was mostly run through voluntary organisations under the aegis of FPAI which received funds mainly from IPPF, Population Council and the FPA of Britain. It was only during the third plan that government agencies began to actively participate in pushing population control. It was at the end of the third plan that Family Planning became an independent department in the Ministry of Health (meaning its status for financial commitments etc. would be increased substantially) and the camp approach was tried out for the first time under the advice of the Ford Foundation. The budget Sky-rocketed from a mere Rs. 2.2 crore to Rs. 25.0 crore (an increase of 1036 percent as compared to only a 128 percent increase for the entire health sector) [Government of India 1982].

During the same time US imperialism had made inroads into the United Nations policy with regard to population control [Mass, 1976]. Following this in 1966 a UN advisory mission visiting India strongly recommended that population growth must be curtailed immediately and for this the resources of the health sector were to be used. "The directorate (Health and Family Welfare) should be relieved from other responsibilities such as maternal and child health and nutrition. It is undoubtedly important for Family Planning to be integrated (it had been integrated with MCH in 1963) with MCH in the field, particularly in view of the 'loop' programme, but until the family planning campaign has picked up momentum and made real progress in the states, the Director General concerned should be responsible for family planning only. This recommendation is reinforced by the fear that the programme may be otherwise used in some states to expand the much needed and neglected maternal and Child Welfare Services" [UN Advisory Mission, 1966].

Taking the cue the Indian government for the first time evolved a traget-oriented approach for sterlisation and the IUD programme. Resources were considerably enhanced and in the first year of its implementation the 'loop' programme netted a phenomenal 8.13 lakh acceptors (much more than sterillisations which had started 10 years before it). And with regard to sterillisations the number of female acceptors also increased substantially.

The above was made possible by redirecting the efforts and inputs of the Third Five Year Plan's ANM-subcentre health scheme, which was mainly designed to reach out health care to women and children, the most vulnerable section of the population. Before this massive investment of the third plan could reach its target, population with the various health programmes — child immunisation, ANC, PNC, domicilary curative services, preventive and promotive health programmes — the imperialist agencies had reoriented the policy to attacking the 'population menance'. Thus the entire basic health care services which were designed for the periphery were reduced to a population control programme at the behest of imperialism. This distortion of an already underdeveloped health sector continues even today.

The population control strategy was based on the imperialist hypothesis that imporved health care necessarily accelerates population growth. [World Bank, 1980; Mass, 1976]. Therefore to check population growth health intervention was to be kept at a minimal level, a level that would generate adequate surplus labour to perpetuate exploitative relations. This was to be realised through heavy financial assistance and export of the ideology of the 'population bomb' by the imperialist powers. The pattern of financial assistance and population growth in

underdeveloped countries is given in Table 2. It shows that the initial lead was taken by private organisations (mostly foundations of the corporate sector) and gradually transferred to bilateral and multilateral agencies through their influence.

(It is also evident that two decades of vast financial commitments did not dampen population growth in underdeveloped countries. Their hypothesis was proved incorrect but this did not decrease their interest in population control. Their own studies in the seventies showed that in underdeveloped countries there were strong economic reasons for high fertility. The nature of the subsistence economy makes it expedient for a household to have a large family so that exploitation of fluctuating opportunities of source of income can be maximised, especially so when most of these opportunities coincide in a particular season — monsoon in India [Chaudhary, 1982]. Also under such conditions children are highly cost-effective. The cost of their raising far outweighs the benifits that arise due to their plenitude children contribute substantially to households through their labour (not necessarily wage-labour) in the fields, outdoor activities (fetching water, firewood etc) and household maintenance (babysitting, cleaning etc.) [Caldwell, 1977; Epstein et. al., 1975; Hull, 1977; Nag, 1978]. Further, these studies also indicated that an important determining reason for high fertility was high infant mortality. The World Bank selectively picked up this latter point [World Bank 1980] and advocated the "child survival hypothesis" to replace the older one mentioned earlier. That is, significant effort needs to be invested in assuring the survival of children so that parents can visibly perceive lower infant and child mortality rates. Thus, instead of direct support to population control activities support to universal immunisation of infants, children and pregnant women becomes the key for achieving lower levels of fertility. Related to the child survival hypothesis is the corollary of 'safe-motherhood'. This corollary is essential because of high maternal mortality and neonatal mortality rates. It is unfortunate that these important issues of survival are being-dealt from the perspective of lowering fertility. In India the current mission approach (Sam Pitroda variety) to immunisation is a case in point. It may be further noted that the issues related to the subsistence economy of underdeveloped countries referred to above have been completely ignored because the underdeveloped countries can overcome their subsistence nature only with the destruction of imperialism.

The Indian state and bourgeoisie have found this imperialist ideology beneficial for their own survival. All problems (especially economic and health) are linked by them to overpopulation. For capitalism and imperialism it is important to regulate fertility because surplus labour beyond a certain level can pose a threat. (The World Bank calls it the spectre of communism). Further, modern capital intensive technology makes generation of surplus labour under capitalism even easier, thus making the need for population control even more urgent.

Population control policy is one area of imperialist intervention in the health sector of underdeveloped countries which has kept health care services underdeveloped in these countries. The other area is promotion of low-cost primary health care for the periphery of these countries.

In India the Narangwal experiment in Punjab in the sixties set the framework for the 'low-cost' 'self-care' approach [Johns Hopkins 1976]. Following this similar experiments and projects were undertaken in Maharashtra and other states by various non-government organisations (Jesani, et.al. 1986). The consequence of this was the questioning of the medical model (especially the Bhore Committee) and promotion of a "community" health care approach. This proliferation of NGO experiments and models became the basis for an important change in the health policy framework of the state. The population control obsession of the health policy of the decade between 1966 and 1976 suffered as set back, albeit temporary, after it had reached its peak during the emergency.

It is interesting to note that the liberal western economies offered full support to the coercive population control activities during the emergency by stepping up their financial assistance for the family planning programme. When in 1976-77 the state's expenditure in family planning increased by 114.6 per cent over 1975-76 (and sterilisation by 204 per cent, assistance by imperialist agencies (bilateral and multilateral) increased by 50.8 per cent in the subsequent year. But when the Janata government came to power in 1977 and government expenditure declined by 46 percent (and sterilisation declined by 88 per cent) the cut in international aid for the subsequent year was 43.4 per cent. And to prove that this was not a mere coincidence the coming back to power of Congress (I) in 1980 increased population control aid by 111.7 per cent [Government of India, 1982].

In the mid-seventies a global change in the health strategy in underdeveloped countries was being worked out by the international agencies. It emerged in the form of Alma Ata declaration of 1978. India had anticipated this earlier with the influence of NGO models which were mostly funded by international agencies [Jesani et.al.1986].

India had officially started with the Community Health Worker Scheme (now called Community Health Guides) in 1977 with the idea of decentralising further the PHC and subcentre model which had failed to work, except in meeting Family Planning targets. There was no guarantee that the CHW scheme would not end up pushing family and planning traget precisely the same thing happened.

Before the introduction of the CHW efforts had been made to integrate the paramedical workers of the vertical health-programmes (malaria workers, vaccinators, ANMs etc.) through the multipurpose worker scheme as suggested by the Kartar Singh Committee. This integra-

tion idea had again emerged from the Narangwal experiment. "The committee unanimously agreed that the concept of multi-purpose workers at the periphery was both the operational research experience of Narangwal, Gandhigram, conclusion" [Giridhar et.al.,1985]. But the integration did not help in anyway in even starting the process of deceleration of the underdevelopment of health in the periphery. On the contrary all the health workers (alongwith many non-health workers, supposedly to justify the promise of interdepartmental cooperation and integration) were laden with carrying the burden of population control targets.

The consequence of this, over the years has been that the state's health care services in the periphery are today viewed by the people as family planning clinics. People in general have developed a distrust for the state's health care delivery system. Thus, thanks (sic) to imperialism primary health care, health services integration and Universal Immunisation Programme 'child survival') have become 'new' flag-carriers of the population bogey.

In the midst of all this for the first time in 1983 an official National Health policy (NHP) was announced. It was largely based on the ICMR-ICSSR Committee Report [ICMR/ICSSR, 1981]. The policy states: India is committed to attaining the goal Health for All by the year 2000 A.D. through the universal provision of comprehensive primary health care services. The attainment of this goal requires a thorough overhaul of the existing approaches to the education and training of medical and health personnel and the reorganisation of the health services infrastructure. Furthermore, considering the large variety of inputs into health, it is necessary to secure the complete integration of all plans for health and human development with the overall national socio-economic development process, specially in the more closely health related sectors, e.g. drugs and pharamaceuticals, agriculture and food production, rural development, education and social welfare, housing, water supply and sanitation, prevention of food adulteration, maintenance of the prescribed standards in the manufacture and sale of drugs and the conservation of the environment. In sum, the contours of the National Health Policy have to be evolved within a fully integrated planning framework which seeks to provide universal, comprehensive primary health care services, relevant to the actual needs and priorities of the community at a cost which the people can afford, ensuring that the planning and implementation of the various health programmes is through the organised involvement and participation of the community, adequately utilising the services being rendered by private voluntary organisations active in the health sector [Government of India, 1983: point 5, pgs. 3-4;]

Very progressive and comprehensive indeed! but all this gets pushed into the background with the paragraph that follows the above: Irrespective of the changes, no matter how fundamental, that may be brought about in the overall approach to health care and the restructuring of the health services, not much headway is likely to be achieved in improving the health status of the people unless success is achieved in securing the small family norm, through voluntary efforts, and moving towards the goal of population stabilisation. In view of the vital importance of securing the balanced growth of the population, it is necessary to enunciate separately, a National Population Policy [Ibid: Point 6, pg.4]

There is ample evidence in implementation of this policy to prove that the population control programmes emphasised in the NHP has been accorded an overriding focus in the "comprehensive primary health care programme" and rest all (specified in the first quote from NHP) is just for the record!

The consequence of this health policy making in India and the resultant programmes with the assistance, guidance and ideological inputs of imperialism has kept the health sector underdeveloped. Even today in India 80 per cent of all health resources and medical manpower are located among the 25 per cent urban population when 75 per cent of the country's population resides in rural areas: even in urban areas 80 per cent of the health resources are accessible only to the top 20 per cent of the socio-economic strata. This shows that the enclave sector structure of health care services continues even today.

Inspite of this apalling situation the government is talking of privatisation of health services : The policy (NHP of 1983) envisages a very constructive and supportive relationship between the public and the private sectors in the area of health, by providing a corrective to re-establish the position of the private health sector.... with a view to reducing governmental expenditure and fully utilising untapped resources, planned programmes may be devised related to local requirements and potentials, to encourage the establishment of practice by private medical professionals, increased investment by non-government agencies in establishing curvative centres and by offering organised logistical, financial and technical support to voluntary agencies active in the health field [Government of India, 1983].

This process of privatisation is not confined to India or to underdeveloped countries but has also been going on in western developed countries which have state supported health programmes. Further privatisation is not limited to the health sector but extends to all sectors of the economy. Privatisation is a response of imperialism both to firm its control of the international economy so that any process of socialisation of production and services is truncated and reversed, and a response to tiding over the fiscal crisis of the state.

This process has begun in India too in a big way. But this is in contradiction to the policy of promotion of low-cost self-care health models. However, this contradiction does not appear sharp because of the enclave structure of our

economy. The high technology and corporate health services are for the few who already have more than adequate health services accessible to them, and the low-cost models are for the periphery.

The low-cost model strategy is a deliberate attempt to keep health care out of the reach of the periphery because without the latter's underdevelopment the over-development of the centre cannot exist. This takes us back to the Bhore Committee model which talked of a level of development of the health sector for India which was on par with developed countries during that time. That level of development is the minimum required if health care services must be adequately available to all. The Bhore Committee also re-commended that health services should be available free of cost to everyone. The rejection of the Bhore Committee report as a policy statement and instead shaping our health services over the years on the whims and fancies of imperialism is one of the important causes in underdevelopment of the health sector in India. Of course the Bhore Committee could only have been implemented if our economic policy had also been radically different.

[Conclusions]

To sum up the discussion one can conclude that the underdevelopment of health care services in India (and similarly in the rest of the underdeveloped world) is part of the process of underdevelopement which is the consequence of monopoly — capital and imperialism. Imperialism controls, monitors and manipulates every aspect of the social structure to the extent that it also expropriates the culture and mind of the population in under-developed countries. Our policy makers, planners are brainwashed and bought over so that our underdevelopment is perpetuated for the development of imperialism. Thus for a small investment in brainwashing and a paltry financial assistance imperialism is able to sell underdevelopment to underdeveloped countries.

Since independence health policy making and the design of health programmes (like all other development programmes) have been guided by programmes of imperialism. The core of the entire health policy and programming of the Indian state has been population control. This has been largely due to imperialism's successful propagation of the 'population bomb' phenomena. As a result the Indian peripheral population has been denied state sponsored health care services (that exist theoretically) and have instead had to depend on the vagaries of the market forces in which operates the overwhelming private health sector that has virtual monopoly of curative health services, being supported to the hilt by the multinational pharmaceutical industry. Today the policy of privatisation is making the scenario for the periphery even worse.

Privatisation, high techonology, population control, low-cost models, aid and the consequent dependency are the means of imperialism to shape our health policy and programmes. Imperialism exploits, expropriates, creates dependency and generates underdevelopment, both within and outside the health sector. And to prevent underdevelopment from getting out of its control imperialism keeps throwing up new tricks (or old tricks in new garbs) each time the contradications of its existence threaten to knock it down. In India too these new tricks have surfaced time and again and have helped underdevelopment survive, even though breathless.

Table 1 : Growth of Health Infrastructure and Investment in Population ('000s) Served Per Rupees Per Capita

	POPULATION (000s) SERVED PER					RUPEES PER CAPITA		
YEAR	HOSPITAL	DISPENSARY	PHC (RURAL)	HOSPITAL BED PERCENT	MEDICAL COLLEGE	QUALIFIED ALLOPATH DOCTOR	DRUG PROD-UCTION	STATE HEALTH EXPEN-DITURE

Health on Political Agenda in Pakistan

SAR

In April 1987 the Pakistan People's Party (PPP) released a well-researched and scholarly document entitled the People's Health Scheme, which together with Benazir Bhutto's speech at that time may be taken to comprise the party's health manifesto. Can the PPP hope to implement it successfully in the event it comes to power?

(Reprinted from Viewpoint, *July 16, 1987)*

THE People's Party has issued a 72-page document entitled the People's Health Scheme. The document was released on April 30, 1987, at a function attended by Benazir Bhutto, whose speech is also included in the document of the party. Given its inclusion, one assumes that it is also part of the document, as it does indeed raise a number of very relevant points.

Before I proceed to the contents of the documents, there are some things which need to be said about the presentation of the document. I have been most impressed by the document, for it is one written by a group of professionals who seem to know their stuff well. The document has numerous references to statistics and publications from the government and international sources, thus giving it great credibility and authenticity. The statistics have not been presented just for the sake of the exercise and a very intelligent and well-researched methodology has been used.

The People's Party is the only political party which has openly and courageously expressed its views on numerous issues, all in published form. Whether one agrees with the contents of the published stands of the party, or with the ideological approach of the party, is something different, but at least we have the opportunity to know its stands and then make a decision for ourselves. Further, despite the fact that some of their published documents have come in for a lot of stick (the Awami budget, the Labour policy), the party has continued the process of making its attitudes public, all backed up by hard facts. It goes to the credit of the People's Party to be able to organise teams of experts on various subjects and then to publish and make public their views.

In her speech which serves as a preface to the document, Bhutto has raised some relevant points about the health system in the country today. She has lamented the plight of doctors, their unemployment and poor renumeration; the role of the last PPP government has been discussed and Benazir has cited the opening of medical colleges, large hospitals, and expansion of facilities under Bhutto; she has clearly understood the causes of ill health when she says "Good health is less the work of doctors and hospitals than of advances in public health. We need improvement in clean water and sanitation; improvement in housing and nutrition"; she has also understood the need for a healthy and educated society in order to build for growth and progress. She has also recognised the fact that of the 10,000 medicines produced in Pakistan, only 250 are needed, as recommended by the World Health Organisation. She has promised to supply the minimum number of essential medicines at very low prices and intends to keep in line with the WHO recommendations.

The salient features of the main report are as follows:

(i) To decentralise the entire health set-up by creating elected District Health Officers — democratisation at the local body level.

(ii) The upgrading of public health services.

(iii) A broadening of the social security scheme.

(iv) The private health sector will be given incentives to improve and enlarge its scope and will be completely separated from the public health sector. General practitioners will be given soft loans for buildings, equipment and cars.

(v) All medical graduates will be given jobs as soon as they finish their house jobs and rural service.

(vi) A National Formulary for drugs based on the WHO list will be introduced and these will be made available even in the smallest villages of Pakistan.

(vii) The obsolete Mental Health Act shall be replaced and new laws according to the present needs will bemade.

(viii) Laws relating to quackery shall be strictly implemented.

(ix) Hikmat and Homoeopathy will be formally organised.

This seems to be a rather comprehensive programme which should be a positive step towards providing 'Health For All' by the year 2000. It is not the purpose of this article to either belittle the programme of the People's Health Scheme, or to find faults with it, or to point out all that could have been said and which was not mentioned in the document (the role of multinational corporations in the provision of drugs). The purpose is to analyse the programme, which on paper seems to be quite good, within the broader social, economic and political structure of Pakistan, for one cannot look at health, or education, or employment, out of a wholistic context.

It is my contention that the problems of health care in the country are linked directly to the prevailing social, economic and political system that determines the alloca-

tion of resources within or outside the health sector. It is this class system which is responsible for the lack of adequate infrastructural and health facilities in rural areas and urban slums and this class system is also responsible for the reluctance of doctors to practise in these areas. Very briefly and in a simplified manner, we can identify five basic issues in the health sector today which affect the distribution and availability of health care.

Urban and Class Bias

The first point regarding the health system which strikes us is that despite the fact that 70 per cent of the population lives in rural areas, most of the medical and health facilities are found in the cities. For example, 85 per cent of the practising doctors work in urban areas giving a doctor : population ratio of 18.01 for urban areas and 1:25.829 in rural areas. In Sind, the rural doctor : population ratio is 1:57.964. For nurses, this ratio in Sind is an astonishing 1:58. Similarly, 23 per cent of the hospitals in the country are located in rural areas and only 8,754 beds are available for a population of 60 million.

This 'urban bias' in health (and almost all other) facilities exists due to a few reasons. For one, the ruling class, whether, bureaucrats, military personnel, industrialists, and even absentee feudal landlords, live in cities and enjoy the fruits of 'development'. Secondly, organised, articulate and politically active groups, such as trade unions, students and professionals, who live in urban areas, have also acted as pressure groups and raised their voices to demand social infrastructure. The elite, the middle classes, and the politically 'noisy' sections of society live in the cities and, thus, it is largely this section which determines the allocation of resources. The 'natural' outcome will be an 'urban bias'.

It must be emphasised, however, that this 'urban bias' is an impressionistic bias and only reflects the geographical location of health services. There exists a deeper and more fundamental bias which is main determinent of access to health facilities. This is the class bias. The facts reveal that not all urban inhabitants have equal access to health facilities, nor are all ruralites equally discriminated against. It may be easier for a feudal landlord to have access to good health care than for a slum dweller in a large city, A 'basti' dweller may have 'apparent' access, in the sense that he may know of existing facilities, but it is not likely that he will be able to afford the high cost of quality private care. At the same time, the quality of care at a government hospital OPD which is available to him, where a doctor has less than 60 seconds for a patient, is indeed questionable. Similarly, for residents within cities, great differences in access exist. Those with money can afford the 'best and latest' technology and have immediate access to facilities, while the majority, like our slum dweller mentioned above, faces innumerable hurdles.

Thus, despite the apparent urban bias, we can conclude that irrespective of geographical location, it is class location which determines access to health facilities.

The purpose of medical education is to produce medical personnel who can work effectively in the existing model of health care in a country. Thus, the doctors produced after six or seven years of training in Pakistan are those who work best in the setting described above: one that is urban-care oriented, and work in the interests of the richer inhabitants of the country.

Medical students in Pakistan are taught from books written in and for the developed countries. The diseases our students learn about are more specific to developed capitalist nations than to underdeveloped ones. For example, they learn from their books that cardiovascular disease and cancer are the main killers, while the real situation in Pakistan is that parasitic and infectious diseases are responsible for 54 per cent of all deaths, while diseases of the rich and of western countries (heart disease and cancer) account for less than 2 per cent of deaths. The teaching methods and books leave such a profound influence on the students that they begin to believe that one of the main causes of death in Pakistan is indeed cardiovascular problems!

Not only does the diagnosis of the disease come from western sources, so does the appraoch to care and cure. The developed country curative care approach is copied in underdeveloped countries where the emphasis turns to urban-based hospitals. The teaching faculty plays a contributory role in accentuating this 'cultural imperialism'. Professors go to the west for training and urge their students to do the same to acquire skills in disciplines such as neuro-surgery and plastic surgery. When (if) these doctors return, they become even more aliented from the masses of their country, who live in urban slums and rural areas. Firstly, they lose touch with common ailments which afflict the poor, such as gastroenteritis and tuberculosis, and can deal best with the diseases of the rich. Secondly, and more importantly, the western-trained doctors are available to only a select few who can afford their high fees.

In underdeveloped countries like Pakistan, where most diseases are of a communicable and preventable nature, the emphasis should be on training doctors who are well-versed in primary health care techniques. Yet, the course in community medicine in medical schools is taken very lightly by students and teachers, who have no real community experience. Often one finds examples where qualified doctors are unable to cope with simple and common problems, such as snake-bite. The training and practical experiences of medical students are solely dependent on their interaction with patients who come to their

urban hospital, again, for a curative approach, when a preventive one may be preferable.

The explanation for this inappropriate medical education is quite straightforward. Since it is the ruling class which essentially determines the dynamics of the health sector, it is also responsible for the production of a specific kind of doctor. This ruling class requires a doctor who works best in a hospital-based curative-care setting and can deal effectively with the diseases of the rich of Pakistan, which are similar to those common in the developed countries. Consequently, the curriculum in medical colleges is designed to produce the desired product.

An important outcome of this type of education and training is the 'westernisation' of doctors. Since doctors in Pakistan are taught about 'western diseases', most doctors can, after some acclimatisation, work easily in hospitals in the developed countries. Our system of medical education has been a major reason for the medical 'brain drain' from Pakistan, with nearly 50 per cent of our doctors practising outside the country.

Had the curriculum been designed to suit the needs of the poor masses of Pakistan, with more emphasis on conditions in rural areas and urban slums, this problem would not exist. At present, given their medical education and doctor migration, the UDC's are subsidising the West!

One would think that, given the poor health status of the population and the poor distribution of facilities, a feature like doctor unemployment would be quite unheard of in Pakistan. But this is not the case. At present, government sources themselves claim that more than 11,000 doctors are unemployed in the country. On the one hand, the country is faced with this unemployment, while on the other, the infant mortality rate is 125 per thousand and the doctor-population ratio in rural Sind is 1:57964.

The crisis of the unemployed doctors has been brewing for a number of years and has only just exploded. Given the policy of successive governments towards health care, this crisis should have been anticipated. Governments have been obsessed with the urban-based curative-care approach and have accordingly built medical schools to provide for the main pillar of the system, the doctor. This one-sided approach to health care has backfired: by not building medical infrastructure to absorb the entire output from medical schools, the doctors have ended up without jobs. Had a more balanced approach been followed, and had facilities been built in accordance with the distribution of population, the doctors may have been able to find jobs, and some may have even considered moving out of the larger cities. Today the situation is indeed ironic and sad that despite the shortage of doctors in the country, the government has advised the unemployed doctors to seek employment in the Middle-East.

In Pakistan more than 7,500 medicines are produced despite World Health Organisation recommendations that only 250 are enough for underdeveloped countries. Significant 85 per cent of total pharmaceutical production in Pakistan is controlled by 15 MNCs!

There are two main reasons for this state of affairs,which is quite common in most underdeveloped countries. Firstly, in a country which supports a doctor-oriented curative-care model, the doling out of medicine becomes an essential requirement of the system. Doctors must have plenty of medicines to give to their patients. If, on the other hand, the approach to health care in Pakistan was prevention-oriented, with intervention taking place much earlier, the need for medicines would decrease and the cure would also be cheaper. The second reason for the continued prominence of pharmaceutical MNCs in UDCs is the link these MNCs maintain with the doctor community and with the state bureaucracy. Many MNCs sponsor international seminars with the ostensible aim of promoting medical science but which are essentially conducted to promote their own product. In many countries doctors are given numerous perks to promote certain medicines. Links with the bureaucracy are strengthened and influence is exerted to ensure favourable treatment in the case of pricing and production.

In the case of Pakistan, little research has been carried out on the pharmaceutical industry and it is time that some scholars took upon themselves the task to do so. It is important not only to know the profit that the MNCs made each year, but also to expose any unethical practices that they indulge in.

In 1978, a revolution took place in the field of health care. More than 130 countries signed a declaration in which they promised to give their people adequate health care by the turn of the century. Pakistan was one of the signatories to the Alma Ata Declaration.

Eight years have gone by since the signing, and only 14 years are left before this century comes to an end. Yet any impartial observer would be distressed by the status of health of the people of Pakistan. Not only have no significant changes been made in the last eight years, given the present trend none can be expected in the next 14. At best one can expect some small cosmetic changes within the warped health care structure in Pakistan, but no real indications exist for the overhauling of the structure itself.

Thus, it is quite clear that health care is a reflection of the social, economic and political structure prevalent in a country. If a small ruling clique controls the resources of a country and little or no participation by the people is

(Continued on page 32)

Continuing Disaster

The minority report of the Supreme Court Committee for Bhopal Gas Victims recently placed before the judges is a telling illustration of the impotency, inertia and inefficiency which charecterises our public funded research establishments. It also highlights a more fundamental issue : the growing signs of an erosion of authority of the judiciary and a disregard for legal processes. Tangentially, the report also draws attention to another aspect of the situation of Bhopal — that the disaster and all its ramifications have remained but a peripheral concern for opposition parties. As a consequence, little pressure has been put on the government, both central and state, to give the disaster the priority it requires.

The committee was constituted in response to a writ petition filed in July 1985 by Dr. Nishit Vora and others who were then in charge of a dispensary administering the only known antidote to the poisoning, sodium thiosulphate. The dispensary had been summarily closed down, its records seized and its doctors arrested. The petition pleaded for a court directive to the state government to allow the administration of NaTS. In August the court issued directions urging the state government to implement a time-bound scheme for detoxification as per the guidelines issued by the Indian Council of Medical Research in April that year. The state government on the pretext of seeking a clarification from the ICMR on the efficacy of the treatment even in August, did not reintroduce the programme.

On a reapplication by the petitioner, the court constituted the Committee for Bhopal Gas Victims comprising experts. Anil Sadgopal represented the petitioners and Dr Sujit K Das was nominated by the members. The committee was asked to specifically give recommendations regarding the detoxification with NaTS, the quality of medical relief being provided to the victims, the use and relevance of the various surveys being conducted at that time for determining compensation and to ascertain what further work needed to be done. In other words, here was an excellent opportunity for reassessing the emerging medical and scientific data and evolve, even at this late stage a programme for health services beginning with detoxification.

In keeping with everything that has happened in Bhopal, the committee muffed the opportunity. After 11 months of desultory functioning all it could come up with was a one-and-a-half page 'report' — the majority report. The committee asserted that NaTS therapy was 'efficacious' and it had been found to be useful in providing symptomatic relief. It concluded that "had the NaTS therpy been provided earlier a larger number of patients might have been benefitted." None of the other issues touched upon by court directive were even considered.

It was in these circumstances that the minority of two dissenting members, Dr Sadgopal and Dr. Das decided to undertake the stupendous task which the committee had opted out of. In doing so the report throws light on the disinterest of members about a matter of life and death concern to the people of Bhopal; it brings out the puzzling reluctance of the committee to call for information from the various institutions or even from the centres in which some of the members worked; and the marked lack of rigour in analysing the data placed before it. This committee it must be stressed was not of merely academic significance; it was constituted at a time when Bhopal's victims were gravely ill and many dying, to work out the best possible programme for detoxification. That it decided after 11 months to confine itself to one single recommendation, and even that on insufficient material is a shocking criticism of the, 'experts' who constituted the committee.

In contrast the minority report delves into a vast amount of data, obtainined with great difficulty. The report painstakingly documents the sequence of events in Bhopal — nothing short of an expose — which has led to the rapidly deteriorating health status

of the population. It once again raises questions which have been asked before but never been answered : Why was the ICMR so lackadaisical about implementing its early guidelines on detoxification ? Why was the state government health administration, especially certain sections of the Gandhi Medical College, so opposed to administering NaTS even when they could very well discern its subjective efficacy ? Even after the government apparently agreed to administer the antidote, why is it that only a miniscule proportion of the total population needing it has received it ? And most importantly, was the basis on which NaTS was prescribed and promoted by activists who took the experts — Dr Chandra's early study and ICMR's double-blind clinical trial — scientifically sound?

Even more significant however, is the report's reveletion that to this day there has been no effort to coordinate the various research projects being undertaken in Bhopal. For instance, although the ICMR listed 24 projects in Bhopal, it does not as yet seem to have made any attempt to collate the findings in order to evolve a broad toxicological perspective. This has meant that there is no cohorent understanding at present of the manner in which MIC has affected the population. The report points out that the possibility of systemic persistence of MIC or its metabolites in the victims and their role in the chronic phase have not upto now become a focus of attention. And yet there were enough data to indicate further investigations in this direction. What is even more puzzling is that three independent studies did in fact propose to focus attention on this matter : Prof Heeresh Chandra's early toxicological study; as early as May 1985 the ICMR postulated the possibility of chronic cyanide toxicity among the victims — the author of this was none other than Dr. S. Sriramachari; and in December 1986, the ICMR update stressed the need to study the "biological effects and metabolism of the toxic principals". And yet the minority members have not been able to obtain any information about these aspects.

In fact the ICMR appears to have been rather adept at compartmentalising its research — this despite having set up a Bhopal Gas Research Centre to ostensibly coordinate the work. For instance, the AIIMS team investigating thyroid activity in the affected population found evidence of persisting toxicity. Surprisingly however, although this too was an ICMR study, albeit not among the 24 listed as Bhopal studies. Not only were the findings disregarded, the project itself was terminated! Similarly, Dr NP Mishra, one of the loudest members of the anti-thiosulphate lobby in Bhopal, was forced to recognise in his October 1987 report for the ICMR the continuing morbidity of his gas-affected patients who had been treated symptomatically. Even this failed to make an impact on the Council's understanding of the situation.

Equally difficult to understand is the fact that investigations on animals exposed to MIC conducted in institutions other than ICMR such as the Defence Research and Development Establishment in Gwalior were probably not even known to the medical researchers. As such they failed to influence the direction of research being conducted over all. The minority members have also failed to discover any material which attempts to integrate the findings of the clinical, toxicological, epidemiological and autopsy findings and analyse them in the perspective of the results of studies on the chemistry of the decomposing products in MIC tank 610.

Part of the reason is of course the shroud of secrecy which surrounds every investigation in Bhopal. The minority members themselves had to contend with this constantly, despite the Supreme Court directive that all information was to be made available to the committee. This raises disturbing questions on the necessity of this secrecy. What was it meant to achieve : to keep information from Union Carbide or was it in fact to keep information from being disseminated to the people ?

— P. P

Problems in Documenting EP Drugs Campaign

anant r s

THE two articles on high-dose EP combination published in *RJH* Vol II. no. 3 do not aim at giving an account of the movement to ban this hazardous drug-combination. But there are certain inadequate or inccurate statements about the same. This response is to correct the unintentional misleading impression created by these statements.

A few activists and journalists belonging to health and consumer groups had gathered in Pune in January, 1983 to discuss and chalk out an action-plan on mutually agreed issues. In this discussion it was decided to take up a campaign against high-dose EP combination. The technical, background material was then prepared by Mira Shiva and Satyamala of Voluntary Health Association of India. V.S. Mathur, Professor of Pharmacology at the post-Graduate Institute of Chandigarh, prepared a 'dear doctor' letter. This was circulated amongst different health, consumer, women's groups and signature-campaign was undertaken. We requested women's groups to include the demand for a ban on this combination, in the list of demands on the International Women's Day March 8 that year. We also managed to get articles published in news papers all over India on March 8 (which was incidentally a Sunday) arguing for a ban on this combination. This was followed up with representations to the concerned authorities.

The second source of determined opposition was in the form of petition in Supreme Court by Vincent Pannikulangara against the continued use of a number of hazardous drugs including high-dose EP combination. The Supreme Court ruling on this petition resulted in the public enquiry.

Thirdly, an article in the *Onlooker* published from Madras, claimed that Palaniappan from Madras has reported a very high incidence of congenital anomolies consequent to the administration of high-dose EP combination to pregnant women. There was a lot of uproar on this issue after this article. Questions were raised in the Parliament.

As a consequence of this determined opposition from different sectors, the Government requested the Indian Council of Medical Research to give its opinion about this issue once again. (Earlier, ICMR had said that there is no need to ban this product; only a warning be given along with the product that it should not be used in pregnancy.) We had argued that this warning, was not going to stop the misuse of this drug. Since there was no scientific indication whatsoever for the use of this combination, consumers would not be deprived of anything if this hazardous combination was banned. This second committee of ICMR also recommended its total ban. It is thus not correct to say that the use of high-dose EP combination "has created such havoc that the victims, i.e. some of the women, could not bear it any longer. Their protests led to the banning of the drug."

The relative success of the campaign on this issue in 1983 was one of the important factors responsible for the continuation of this networking that had taken shape around this issue. The All-India Drug Action Network, consisting of around a dozen health, and consumer groups, was born and continued to follow-up the demand for a ban on high-dose EP combination.

In the public hearings on high dose EP combination, member-organisations of All-India Drug Action Network have played a significant role. The method of publishing the notice about the public hearings in an inconspicuous manner and not informing the concerned action groups was severely criticised. So also the reported decision of the Drug Controller to stop the hearings after the Calcutta hearing. Fraternal organizations outside AIDAN, like FMRAI and Health Service Association of West Bengal also put up a lot of pressure on this issue. As a result of these efforts from different groups, the Drugs Controller had to decide to hold hearings in Calcutta and Bombay and had to send invitation-notices about these public hearings in Calcutta and Bombay to all the concerned groups. Mira Shiva (VHAI), Satyamala (MFC), Vishwas Rane (Arogya Dakshata Mandal), Amit Sen Gupta (Delhi Science Forum) gave a valiant fight at the Delhi hearing even though the pro-EP forte lobby was in the majority, had a few prestigious gynaecologists on their side. All these organisations are members of AIDAN. In the Bombay-hearing also ACASH, ADM, MFC, LOCOST—(all members of AIDAN) along with other similar groups presented a solid technical case against high dose E.P. combination, whereas various women's groups presented a social critique of the continued use of this combination against the interests of women. Amitav Guha's article, unintentionally glosses over the role of AIDAN in this movement.

The movement against high dose EP combination thus does not follow a classic pattern. It was not initiated by any women's group, nor did the women's group consistently follow up this issue, or took a lead in it. A lawyer (Pannikulangara), a journalist of *Onlooker*, a few committed health-activists from certain health-action groups (some of which are incidentally foreign-funded) played at least as important a role as women's groups or the trade union FMRAI, alongwith many others, did AIDAN remained the

'Cut System' Dilemmas

murlidhar

forum which helped to pursue the matter and helped to co-ordinate the lobbying.

The above clarification is not at all meant to be a criticism of women's groups but to communicate as to how things took shape in reality. It indicates that sometimes initiatives are taken, events occur in such issues in health in a rather unexpected manner. What is the significance of this unorthodox picture? What are the lessons to be drawn? I hope, that there would be some discussion in *RJH* on this topic.

Today a friend of mine, a consultant earned Rs. 100/ -- out of which he gave Rs. 60 to the ever willing hands of the local GP. This patient had come to him with a diaganosis of 'chronic' appendicitis. The G P instructed my friend to get a host of investigations from a specific pathologist and a radiologist who in turn give their respective cuts to the GP. All his medical teaching was of no avail as he unnecessarily subjected the patient to a host of investigations and unnecessarily operated on a patient who actually had a mild attack of Amoebic typhlitis.

It is said that nearly 80 per cent of private health practice is part of this nexus of commission and cuts between the GP and the consultant. They go to any lengths to earn their bread and butter and probably, jam. They may be part of the so called 'Arab practice' or the 'Kidney transplant nexus'. They admit patients in their ICCU's with a (mis) diagnosis of an infarct. They manage seriously ill patients till they become critical before sending the patient to a general hospital. They even have nexus with the Medical representatives who give cuts for prescribing a particular drug albeit spurious or banned like EP forte for example.

The health services of our country like most others like pharmaceutics is an industry in itself. It is profit-oriented. All the state run health services are poorly equipped to deal with the illnesses of 700 million people, the government is not interested in providig better facilities, because of the poor cost-to-profit ratio. The drug industry is the second most profitable industry in the world after the arms industry. Hence there is flooding of spurious, banned and bannable drugs in the market.

Where does a doctor figure in the above maze of profit-oriented industries?

On one hand is what we have learnt and understood for the past 26 years, on the other is the pull exerted by the profit-oriented industry. Most of us do not have a capital to rely on, hence, tend to get pulled to the latter side. If we resist, then there is a theoretical possibility of falling into the abyss between the two philosophies.

We have to choose whether we are going to practice rational medicine or whether we are going to join the rat race. The latter choice is irreversible. If we choose the former, we can set an example for others to follow and hope that the profit oriented economy of drug and health services will surely meet its hour of crisis when the average patient says in unison "I cannot stand it any longer". Can we stand the test of time?

The irrational 'cut' practice was not so prevalent say 50 years back. At that time our elders insisted that honest, and ethical medical practice is important and unethical practice is to be shunned. Now, the same elders and colleagues say that if one wants to just about make both ends meet, he should practice irrationally. Why has it changed so drastically?

Even at that time there were two types of health services, namely 1) private practice and 2) the state run hospitals supposedly working selflessly. Over the last 50 years, a lot of money was poured in to set up large-scale drug industries or extensive diagnostic centres. The above works only to increase the invested money. The owners do not think about the average consumer but only in the amount of profits they get.

The health budget of the state of Maharashtra is one of the highest. It is believed that the effects of the increased budget would 'trickle' to the bottom increasing the health status of the millions of exploited in the city. Actually it appears as if that it has had no effect at all. Otherwise nearly 100 infants would not be dying of every 1000 live births or 50,000 people would not die of TB every year or thousands would not become blind every year due to lack of Vitamin A!

Let's now look at private practice in this respect. The private doctor is no longer an independent healer. He is part of the system whose owners are interested in the profitability of their drug enterprise or the diagnostic or therapeutic equipments. He is controlled by the very system that promotes the increase of capital at the hands of few industry owners. He no longer practices rational medicine. His idealism remained purely theoritical that is taught in the sheltered class -room of a medical college. He becomes a commodity that can be bought and sold by money.

Is it possible to fight this manace? If so will we get support from colleagues or others who are passing through the same process in other fields?

(Continued from page 27)

tolerated, then the health sector will reflect this pattern, with health for a few and not for all. To bring about a revolution in health, it becomes necessary to bring about a revolution in society. The experience of socialist-oriented societies shows that once they have changed the pattern of the distribution of resources within the society, they have been able to change the pattern of health care, making access more equitable. Apart from socialist countries, some social democratic nations with a long history of participation by the masses have also provided adequate health facilities to their people and the resulting improvement in their health status is quite enviable. Thus, one cannot expect significant improvement in the health sector in Pakistan without substantial participation of the masses in the workings of society, and without substantial changes in the power structure as it exists today.

So, where does the well-meaning People's Health Scheme fit into all this? The People's Party is a populist party which means that it cannot and will not change the basic economic and political power structure as it exists in the country today. Thus, one cannot expect that it will drastically change either the health system or substantially increase the accessibility of health services. It is true that under the Bhutto regime, the expenditure on health care was much greater than it has been since 1977. But, caught up in a pseudo socialist populist trap, the policies followed looked good only on paper. The eight medical colleges built in the country were created to appease the noisy middle classes. Had the government really been sincere it would have built rural health centres and basic health units instead of these great buildings called medical colleges. (For the cost of one medical college, 251 rural health centres or 556 basic health units could be built which would serve 5.56 million people - all of whom live in rural areas!).

Thus, the People's Health Scheme is a step in the right direction, and one can assume that some changes on the margin will indeed be made. However, meaningful radical change in the health sector, which would truly and honestly serve the people, will only come about once the existing social, political and, most importantly, economic relations are broken.

REPRODUCTIVE AND GENETIC ENGINEERING

[Journal of International Feminist Analysis] [(published three times in a year)] RGE is designed to facilitate the development of feminist multi-disciplinary and international analysis on the new reproductive technologies and genetic engineering and their impact on women worldwide. The policy of the journal is to recognise the use and abuse of women as central to the development of reproductive technologies and genetic engineering and to highlight the relevance of the application of these technologies to the past, present and emerging social and political conditions of women.

RGE is edited by International Editorial Collective and Editorial Advisory Board.

HUMAN RIGHTS ETHICAL CODES AND DECLARATIONS

Doctors and Torture

TORTURE is condemned universally as inhuman and as a calculatedly cruel practice. As such it should not find any place in any civilised society. Yet its widespread use is a truth that cannot be denied. To a greater or lesser extent it is resorted to in all countries. Why is this so? Why do countries which apparently place a high value on human rights routinely practise and condone physical and mental abuse of its opponents both in times of war and in peace?

Torture has been recorded in history since the ancient times and there have been references to torture in the 12th and 13th centuries, and even earlier. The Tudor and Stuart monarchs made frequent use of torture. But it was during the religious and political struggles of the 16th and 17th centuries in European countries that there was more open discussion of the subject. Indian history also is replete with references of torture of political prisoners.

It was in the 18th century that a movement against this cruel inhuman practice was initiated with the hope that by the end of the 19th century this practice would be abolished altogether. But the reality of concentration camps in Germany under Nazi rule, with their largescale use of torture wiped off this optimistic belief. However, it was in the aftermath of the war and the end of Nazi rule that serious attempts were first made to set out norms of conduct for medical people participating in torture.

Torture is among the most reprehensible aspects of state repression. Unlike other forms of repression, it can be carried out in private and in such a manner that none but those against whom it is used come to know of it. So it can be practised with impunity within smiling democracies professing to be 'open' societies ensuring freedom of speech, expression etc. to its citizens.

Torture is used to suppress dissent against the state and its ideology in various ways. It is used extensively to extract information—and this use is often protrayed as being justified in order to maintain 'law and order'. But more importantly, it is used to strike terror in the hearts of those who oppose it. A torture victim becomes a warning to others who may follow his/her path for much the same reason that feudal barabaric societies displayed severed heads or conducted public hangings.

The Indian state has consistently and widely used torture to quell rebellion and protest whether it is to supress movements of minorities for autonomy or those which pose an ideological challenge to the state. In Telengana in the 40s and Naxalbari in the 60s and 70s and Bihar, Punjab and Andhra Pradesh in the 80s the state's police have systematically and routinely used torture on political prisoners so much so that they have perfected methods which cause pain and suffering to the individual but leave no mark which can be displayed to monitoring authorities, such as they are. And in all this at some level or other—whether in diagnosing and treating a victim of torture or in issuing death certificates of those who have succumbed to it or in many other numerous small ways—is involved a health worker most often a medical professional, who ironically enough is pledged to preserve life and reduce suffering.

Here there are two aspects which must be touched upon. Usually torture in most codes is defined to mean the abuse of person in the custody of the authority. In a larger sense and increasingly, it includes the physical and mental abuse meted out to the friends, relatives and others close to the victim. Again the evidence of torture becomes valid only with the involvement of the medical profession. Secondly, sexual abuse and assault on women held in custody or held for 'questioning' is becoming increasingly frequent. And in most cases, it is medical evidence which will help in bringing the victimisers to book. The medical profession thus plays a crucial role in protecting human rights.

The United Nations, in 1975, in its Declaration, has defined torture as: "Torture means any act by which severe pain or suffering, whether physical or mental, is intentially inflicted by or at the instigation of a public official on a person for such purposes as obtaining from or a third person information or confession, punishing him for an act he has committed or is suspected of having committed, or intimidating him or other persons. It does not include pain or suffering arising only from, inherent in or incedental to, lawful sanctions to the extent consistent with the Standard Minimum Rules for the Treatment of Prisoners. Torture constitues an aggravated and deliberate form of cruel, inhuman or degrading treatment or punishment." (see *Health and Human Rights*, ICHP/cinpros 1986, p 25). As Paul Sieghart states (p 95) the "prohibition against torture contains no limitations or exceptions of any kind and *allows no derogation in any circumstances—not even in times of war or public emergency treating the life of the Nation*" (Emphasis added).

Doctors As Victimisers and As Victims

It is an irony that the "protectors of law and order"—the police themselves employ the method of torture which is so universally condemned but what is unthinkable is the involvement of doctors (actively or passively) in torture, particularly when they happen to be police, prison or military doctors. The conflict between the ethical positions of the prison doctors and national laws are real and superficially bewildering but certainly not unresolvable

As Dr. Wyner of the World Medical Association clarifies "that if a certain legislation is criminal and contrary to ethics, the doctor has the deontological duty to ignore it and in some cases, even oppose it when practicing his profession". It is thus gratifying to learn and in Switzerland, the prison doctors and subordinate medical authorities alone are responsible for the prisoners' health and thus find it easy to maintain the patient-doctor relationship. Such a trend must spread to other countries as well.

So far as the ethical codes on the subject are concerned, there need be no ambiguity in the mind of the medical practioner. The UN Declarations and codes relating to Principles of Medical Ethics, the Declaration on the Protection of All Persons from Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment and (iii) Standard Minimum Rules for the treatment of Prisoners and related recommendations are amply clear and concise to permit any grey areas. Furthermore, the statements by various orofessional associations viz. that of (i) physicians, (ii) psychiatrists, (iii) nurses and (iv) psychologists, also leave no stone unturned in respect of the ethical positions. [Elsewhere in the issue we carry the full text of some of there codes and statements]

Even so, there are reports revealing medical practioners attending the interrogation of punishment centres for examing the detainees to certify on their health and later administering treatment for the victims' injuries. Some of them are even reported to be active in torture. How else could one explain some of the more modern and sophisticated methods of torture which could not have been devised without the active participation of experts (forensic) having a high degree of knowledge in the area? To the extent that many of its members contribute to torture, the whole medical fraternity must also share his guilt and it is for the respective medical councils to pull up its members. Medical fraternity must do all that is in its collective power towards eliminating this obscene, cruel, inhuman practice that is internationally outlawed.

The doctor compounding or assisting torture discarding the ethical norms is obviously only one facet of the situation existing today, but consider the scene where (and this is known to take place more after in some countries under some dictatorial regimes) the doctor has had to pay heavy penalties including his life for having listened to his consciense and abiding with ethical codes laid down. Often a doctor is penalised for helping the victim of state repression or for supporting movements for justice. One such victim of police brutality was Dr. Ramanadhan who was shot dead the state police in September 3, 1985. We publish in this issue a short biographical sketch of the doctor-activist. Undoubtedly, health workers who use their professional skills to help those who protest against the state are themselves vulnerable. Particularly under the dictitorial regimes the reality is such that people's protest against such actions cannot be expected to operate. International pressures need to be applied and the Human Rights wing of United Nations have a pertinent role in this.

What about the repurcussions of torture on physical and mental health of the tortured? On the family? And the responsibilities of medical and social scientists in this matter? It is clearly imminent that torture would both physically and more importantly mentally wreck the victims' and ruin them and their families but sadly there are not enough studies on this important issue in our country [see the case of Archana Guha in this issue]. Such studies, if nothing else, could serve well towards eliminating the apathy towards this distantly occuring nonetheless sensitive issue. Surely it must be remembered that until empathy towards the tortured does not percolate through vast multitude of peoples, elimination of this inhuman practice will keep eluding us time and again.

Why have we chosen to highlight the issue of the role of the health worker in preserving human rights, especially in state torture? Firstly, because as we have seen, the medical profession plays a crucial role both in perpetrating torture but also in publicising its use and bringing the victimisers to book. In doing so, the health workers themselves become vulnerable to attack. It is therefore necessary that a strict code of conduct be implemented. Also, doctors who are placed in vulnerable situations must be ensured safety. In times of war, for instance, medical help is always ensured safe conduct. In times of peace too, it should be possible to safeguard the life of people who give medical aid.

Secondly, there has been an increasing incidence of police torture and inhumanity. With the growth of political awareness, mass movements are on the upswing. The state is bound to become more repressive and if this repression is to be effective while maintaining the facade of democratic functioning, it has to use such instruments which focus on the individual and are hidden from the public eye. There is a tendency to legitimise torture (say, by branding the victims as 'terrorists'). Again there is need to create an awareness of where, how and in what circumstances torture takes place and the role the health worker plays in this. It is also necessary to empower them with information on how they can be coerced into abetting torture and what they can do about it.

While we highlight some of the major issues in the field and how the international community of health workers have tackled it this is certainly not the last word on the subject. There is a particular lacuna about information on India. We hope the issue will generate discussion on the issue and lead to documentation of the Indian situation.

Anil Pilgaokar

Medicine at Risk

Doctor as Human Rights Abuser and Victim

Amnesty International

For over a decade now, the Amnesty International has been working to eradicate the use of torture. In this effort, it has paid special attention to the role of health workers in human rights violations as well as the violation of the human rights of people working in health.

[This paper was prepared by the International Secretariat of the Amnesty International and circulated as a background paper for the International Seminar on the same subject at Paris from January 19 to 21, 1989.]

IN 1978, Amnesty International convened an international meeting in Athens which brought together some 100 health professionals from 13 countries to discuss 'medical detection and effects of torture, the need for treatment, rehabilitation and compensation of torture victims, and other work of the medical profession against violations of human right'. Among the many conclusions and recommendations made by the participants, three themes were identified for continuing study and campaigning. Two of these particularly relevant to the subject of 'medicine at risk' were strategies for the prevention of torture, and the elaboration of medical ethics codes against torture [1].

Despite continued widespread human rights violations, there have been since 1978 a number of positive developments with regard to prevention of medical involvement in torture and two in particular might be mentioned here. The first was the adoption by the United Nations General Assembly on 18 December 1982 of the Principles of Medical Ethics Relevant to Health Professionals, Particularly Physicians, in the Protection of Prisoners from Torture and other Cruel, Inhuman or Degrading Treatment or Punishment. These, together with the World Medical Association's Declaration of Tokyo of 1975, offer the clearest ethical guidance to the health professional confronted with the problem of torture.

The second encouraging development has been the active public opposition of some medical and other associations to torture and their commitment to disciplining those health professionals who participate in it. However in the face of continuing human rights violations and despite committed work by human rights groups and professional bodies [2], a wider degree of engagement by health professionals in supporting colleagues at risk would make a significant contribution to the fight for human rights.

This paper reviews some of the issues implicit in the theme 'medicine at risk': that is, participation of health workers in human rights violations, the violation of the human rights of those working in health care; and the role of professional associations in dealing with these abuses.

Human Rights Standards

Human rights violations are contrary to the principles of all the healing disciplines. Ethical standards of a wide relationship of the practitioner and his or her client should be based, *inter alia*, on principles of beneficience and respect for the client's autonomy.

However, dealing with prisoners poses certain difficulties to medical and other personnel since prisoners have lost their freedom with concomitant restrictions on their autonomy; secondly, the health professional has obligations with regard to the detaining authority which they may see as threatening the concept of medical confidentality, in practice if not in principle. Nevertheless, the ethical standards have been clearly set out.

The World Medical Association, at its assembly in Tokyo in 1975 adopted a declaration which stated that it was prohibited for a doctor to "countenance, condone or participate in the practice of torture or other forms of cruel, inhuman or degrading procedures, whatever the offense of which the victim to such procedures is suspected, accused or guilty. . ." [3] The World Psychiatric Association, in its Declaration of Hawaii [1977] stated, *inter alia*, that "no procedure shall be performed nor treatment given against or independent of a patient's own will. . ." and "the psychiatrist must never use his professional possibilities to violate the dignity or human rights of any individual or group. . .".

Nurses' and psychologists' associations have also set out the responsibilities of these particular professions with regard to the care of those in detention.

An international code applying to all health professionals— The Principles of Medical Ethics—which embodied many of the elements of the Declaration of Tokyo, was adopted by the United Nations on December 18, 1982. This states categorically *inter alia* that it is a contravention of medical ethics for "health personnel, particularly physicians, to engage... sub acts [of] torture or other cruel inhuman or degrading treatment or punishment".

Unfortunately, in spite of the elaboration of these comprehensive standards, there is irrefutable evidence that in many countries professional expertise continues to contribute to human rights violations.

These breaches of professional ethics are manifested in a number of ways, including participation in the practice of torture. Direct involvement takes a number of forms:

Examination of prisoners before interrogation to ensure that the prisoner can survive torture or to find sen-

sitive foci for exploitation during torture.

To monitor the torture process: to stop the torture if it threatens the prisoner's survival or to resuscitate the victim where necessary.

To 'patch up' the victim after torture, possibility to undergo further sessions or to make the prisoner presentable for appearance in court or after release.

To provide the police or other authorities—under pressure or by free will—with false certificates stating that the prisoner is in good health or, in event of their death, certifying a false and misleading cause of death.

To advise the torturers or to directly use medical or psychological techniques during interrogation eg. giving sensitive information obtained during the interview or helping administer drugs [4].

Other abuses of medical expertise constituting infringements of medical ethics and human rights include:

Falsely certifying that an individual is seriously mentally ill in order to have them committed forcibly to a mental hospital so as to curtail their political activities.

Advising executioners of the progress of an execution to enable them to continue or to modify whatever technique they are using.

Using medical skills to mutilate an individual as a punishment or advising others in the application of such skills. [5]

Reasons for participation by health professionals in behaviour of the kind cited above can, for the most part, be the subject of speculation only; most of those who take part in torture do not set out their reasons for doing so [6]. However there is enough evidence to suggest that the motives [or rationalisations] include some of the following:

Fear of consequences of refusal or seeing open opposition to abuses as an impossibility for whatever reason. Doctors under military discipline may feel, like others, that they are under irresistable pressure to participate. In his study of the behaviour of Uruguayan physicians during the period of military rule [1973-1985], Bloche could identify only *one* health professional working with political prisoners who openly refused to collaborate in abuses [7].

Identification with the cause of the torturers and a belief that serious measures are justified by what are seen as serious threats to national security. The Chilean Physician Alfredo Jadresic cited a young doctor explaining his collaboration in military abuses at the Chile stadium after the 1973 coup in these terms: "What do you expect? We are at war."[8]

Defining the doctor's function as essentially a bureaucratic one. A female Uruguayan prisoner testified to pleading with a doctor to obey his physician's oath; she said that he replied: "I'm just doing my job" [9].

Inadequate understanding of professional ethics: for example, to see it as the health professional's job to minimise suffering resulting from torture or ill treatment through participation in the interrogation process.

The psychological mechanisms and ideological analysis by which doctors have justified participation in systematic human rights violations have been examined in depth by Lifton [10] with respect to doctors in Nazi Germany, and more briefly with respect to Uruguay during the military government of 1973 to 1985, by Bloche [11].

Lifton suggested the concept of "doubling"—ie. the creation of a second self who could participate in a lifestyle and professional conduct which might ordinarily be seen as in conflict with the individual's underlying moral and professional values. He refers to the 'technicalisation'of the medical role [dissociating the technical aspects of their function from the moral values associated with it] and a related psychological distancing. [Lifton points, for example, to doctors'participation in selection of vic tims for the gas chambers, noting that "by not quite seeing it, they could distance themselves from the very killing they were supervising; selections could be accepted as an established activity and seem less onerous than specially brutal tasks [such as medical collusion in torture to produce confessions]..."; pp. 199-200]. He suggests [p. 200] that such a view could also be interpreted that selection for killing was so onerous "that Nazi doctors called forth every possible mechanism to *avoid taking in psychologically what they were doing* [emphasis in original]. Other authors have dealt more generally which the motivation of tortures [12].

Participation in Violations of Human Rights

Evidence of the participation of health professionals in abuses of human rights is, unfortunately, readily found but perhaps not widely discussed or acknowledged. The report by the British Medical Association on doctors and torture, published in 1986, concluded that "the evidence given to the [BMA] leaves no room for doubt that doctors are involved in many parts of the world in the physical and psychological torture of prisoners."[13].

Documents published by AI both before and since the publication of the BMA report as well as reports from other medical associations [Chile, Uruguay, Turkey] and organisations [such at the American Association for the Advancement of Science] all confirm this phenomenon.

Abuses of psychiatry for political reasons have been documented in the USSR, Czechoslovakia, Romania and Yugoslavia, though the role of psychiatrists in these abuses probably varies from those who knowingly falsify a psychiatric diagnosis with the express purpose of colluding in the imprisonment of a political or social nonconformist to those whose role is more passive and who fail to protest at the failure of the legal system and their

own colleagues and superiors to protect individuals from such abuses. The motivations of psychiatrists involved in these practices probably include genuine belief in the diagnoses such as 'sluggish schizophrenia' [14] as well as conformist, bureaucratic and ideological reasons [15].

With regard to the death penalty, the role of the health professional is not well documented apart from the case of the USA where there has been a vigorous debate on the ethics of professional participation. Physicians have argued against [16] and for [17] physician involvement in execution by lethal injection, though the American Medical Association has made clear that any involvement would be unethical.

The American Psychiatric Association and the American Nurses Association have both ruled participation unethical though some psychiatrists still present evidence based on hypothetical questions relating to the defendant's "future dangerousness" in death penalty cases [where their evidence can be highly influential in securing the death penalty] despite the view of the APA that such testimony has no value as expert testimony since psychiatrists are no more accurate in such predictions than non-psychiatrists [18]. The ethics of such behaviour has yet to be ruled upon by the APA.

The involvement of health professionals in certain other human rights violations—flogging, amputations, prolonged solitary confinement—is more contentious since these abuses are provided for by a law in some countries and doctors' presence at their infliction may be specified in law. However, some individual doctors and some medical associations have nevertheless protested at such punishments being carried out in their country. For example, the Mauritanian Association of Doctors, Pharmacists and Dentists expressed 'deep concern' at the involvement of physicians in the punitive amputation carried out on three convicted thieves in September 1980. Another amputation took place in June 1981 and again a doctor was involved though it was reported that two amputations carried out in 1982 were executed by a medical auxiliary following refusal by doctors to assist. In Pakistan, both the Karachi branch of the Pakistan Medical Association and the Pakistan Junior Doctors, Association voiced their concern about flogging of political prisoners.

"The problem with torture", concludes the BMA report, "is not whether it is right or wrong. It is how to detect the subtle changes in relationships which lead to the doctor's acquiescence in torture." It continues:

> The experience of those who gave information to the [BMA] demonstrates that a refusal to compromise is effective in the early stages, firstly because the doctor himself is less likely to be compromised and secondly because the apparatus of the state is likely to be vulnerable to concerted public opposition. Once these early stages have been allowed to pass unchallenged, it may be too late to avoid serious abuse. [19]

Violation Against Health Professionals

Reasons for repressive measures being taken against health professionals include: (i) their real or perceived peaceful or violent political activities against the government; (ii) their activities in human rights groups; (iii) their professional activities or criticisms of government health policy; (iv) their giving treatment to injured armed opposition; (v) the perceived deterrence value of making an example of the health professional; (vi) accidental reasons [for example, being in the wrong place at the wrong time].

In many, perhaps most cases, persecution cannot be simply attributed to one unique reason. Doctors who are active in political opposition groups may also be engaged in human rights activities. Similarly, those who criticise health standards or government policy on health may also be seen as politically active, or involved in human rights action and so on. While the rights of doctors to participate in political activity must be protected in the same way that any citizen's political rights should be protected, the particular focus of this paper is the risk of doctors being victimised because of their professional or human rights activities.

The actions which precipitate repressive measures can, in some cases, be substantially attributed to human rights activities: the attacks are focussed and concern individuals whose prominence owes a lot to their position as a human rights activist.

In Colombia for example, two doctors active in the Committee for the Defence of Human Rights [CCDHM] were the victims of political killings in 1988. On 25 August 1988, Dr Hector Abad, aged 65, and Dr Leonardo Betancur, aged 41, were shot as they were leaving a service for the president of a teachers' union who had been killed that morning. Dr Abad, who was a former Dean of the Medical School, reported receiving death threats shortly before his murder.

In the USSR, those involved in the work of the unofficial Moscow Working Commission to Investigate the Use of Psychiatry for Political Purpose were detained in connection with their work in documenting the practice of internment of prisoners of conscience on spurious psychiatric grounds. Dr Leonard Ternovsky [b. 1933], a radiologist, was arrested on April 10, 1980 in Moscow and was charged under Article 190-1 of the RSFSR Criminal Code with "anti-Soviet slander". He was subsequently convicted and sentenced to three years' imprisonment. Other members of the Working Commission were also imprisoned in the period 1980 to 1981, culminating in the sentence of 12 years' imprisonment and internal exile for Dr Anatoly Koryagin, the psychiatric consultant to the Working Commission, following the publication in the British journal *The Lancet* [20] of a paper describing his experiences of the misuse of psychiatry for political purpose.

More widespread and indiscriminate repression occurred in Syria during the period 1978 to 1980, when there was pressure on the Syrian government from lawyers and other professionals to implement measures included lifting the State of Emergency in force since 1963. In early March 1980, meetings of dentists, pharmacists, engineers, lawyers, teachers and medical association representatives in different Syrian cities urged the introduction of reforms. On March 21 1980, a general conference of the Syrian Medical Association met in Damascus and passed a resolution which included the following demands:

> Re-affirmation of the principle of the citizens' rights to freedom of expression, thought and belief;
> Denunciation of any kind of violence, terror, sabotage and armed demonstration, whatever the reasons and justifications;
> Abolition of exceptional courts;
> Release or trial of all detainees

On March 31 1980 a one-day strike was called by lawyers in Damascus and this was supported by other branches of the Bar Association and by other professional associations including members of the Syrian Medical Association. Shortly after the strike, the national congress and regional assemblies of the Medical, Engineers and Bar Associations were dissolved by the Syrian Ministerial Cabinet. In the days that followed the dissolution, numerous lawyers, doctors and engineers were arrested and held without charge or trial. At least two doctors were later executed and some 100 doctors remain imprisoned still without charge or trial more than eight years after their arrest.

In Central America, a wide range of health professionals were subjected to intense repression in El Salvador and Guatemala in the period 1980-1982 and in a less intense way in subsequent years. Some of the victims of the torturers and 'death squads' were active government opponents but the institutionalised nature of the abuses and the impunity with which those perpetrating the human rights violations could act meant that those with little or no political engagement were also victimised.

In July 1980 a United States Public Health Association Commission visited El Salvador and reported an alarming pattern of military incursions into hospitals and abduction and murder directed against health personnel. Their report listed 23 health professionals who were killed or had disappeared in the period January to June 1980. Many were tortured before their murder.

In Guatemala, an equally disturbing pattern of attack directed against health workers was occurring. On April 23 1981, a 32-year-old doctor, Dr Otto Raul Letona, was shot 12 times in the torso by unidentified gunmen as he stood in the emergency ward of a hospital in Antigua, talking to a patient. Another 13 medical personnel were reported killed during the first half of 1981 alone.

In both El Salvador and Guatemala, being involved in providing health care to the rural poor appeared to be linked—in the view of the military—with subversion and opposition. The widespread and indiscriminate nature of the repression particularly in the early 1980s suggests that the definition of subversion was very loose and could be applied to anyone working to improve the situation of the peasants. In some cases, doctors *did* treat members of armed opposition groups or individuals who had sustained bullet wounds; occasionally doctors were detained for giving this help though it was much more common that a doctor suspected of 'aiding the opposition' would be dealt with extra-judicially.

Where torture, 'disappearance' and political killings are everyday realities [as in El Salvador and Guatemala during the period under consideration], the options for a health professional appear rather limited. Even if they wish to remain outside politics they are obliged to ensure that anyone with injuries should receive medical care and must, as a consequence, evaluate the best way to ensure the physical security of their patient. A number of cases have been documented where medical personnel have not reported patients with bullet wounds as required by law in circumstances where they could reasonably fear that reporting would lead to their patient being tortured or killed. This action in itself may make the doctor a target for human rights violations.

Since 1980, Amnesty International has issued medical appeals on behalf of health professionals in the following 30 countries: Afghanistan, Algeria, Argentina, Benin, Chile, Colombia, Cuba, Czechoslovakia, El Salvador, German Democratic Republic, Guatamala, Iran, Laos, Nepal, Paraguay, Republic of Korea, Romania, Singapore, Somalia, South Africa, Sri Lanka, Sudan, Taiwan, Turkey, Uganda, USSR, Uruguay, Vietnam, Yugoslavia, Zaire.

Role of Professional and other Associations

The central role of professional associations in assisting health personnel at risk of being pressured into collaborating in, or remaining silent about, human rights violations is alluded to in the last article of the WMA's Declaration of Tokyo. this states that:

> The [WMA] will support, and should encourage the international community, the national medical associations and fellow doctors, to support the doctor and his or her family in the face of threats or reprisals resulting from a refusal to condone the uses of torture or other forms of cruel, inhuman or degrading treatment.

Unfortunately, in many cases the associations themselves are under severe threat or acute repression. As noted above the Syrian Medical Association was dissolved after calling for human rights reforms in 1980; members of the Turkish Medical Association were prosecuted in 1986 for calling for an end to the death penalty in Turkey; the Chilean Medical Association was raided by security agents in 1986 at the time it was organising a meeting with international participation on the

theme of the role of medical associations in the protection of human rights.

However, it is striking that medical associations and other professional bodies in countries where abuses occur systematically have frequently *not* spoken out against them nor taken any apparent action against health professionals collaborating in torture, covering up deaths following ill-treatment or carrying out other unethical acts. Individuals doctors seeking support from their association or an obvious body to whom to complain, may interpret the silence of the professional association [sometimes correctly] as a disinterest in the issue or an unwillingness to speak out. If the professional leadership will not speak out, the pressure on individuals to remain silent is all that greater [21].

Recently, the Uruguayan Medical Association has been active in promoting the idea of an international medical forum for the hearing of evidence of medical abuses against human rights. This idea was recently supported at a meeting in Geneva in October 1988 of the International Council of Health Professionals. Some specialist groups of professionals have looked at ways of using their own expertise to counter human rights violations. For example, forensic scientists have contributed to the drafting of a protocol for the investment of deaths in detention or in order circumstances where a proper investigation of the cause of death should be instituted [22], and have participated in a number of investigations which have had the objective of clarifying the fate of persons whose deaths have been the subject of deliberate cover-ups.

While professional associations have a major role to play in disciplining their members who assist human rights violations and protecting members who are active in promoting human rights or who resist pressure to collaborate in torture, other bodies also have an important role. Human rights bodies can help translate and circulate information, endeavour to break down isolation and give support to both opponents and victims of torture and other bodies; they can press governments to fulfil their international treaty obligations; and they can offer international solidarity—something which has been remarked on as being of great support to those facing repressive governments.

Notes

[1] The third was the rehabilitation of torture victims. See *Violations of Human Rights: Torture and the Medical Profession.* Report of an Amnesty International Medical Semianr, Athens Mach 10-11 1987. AI Index: CAT 02/03/78.

[2] One of the associations which reversed a previous quiescent stand on human rights was the Colegio Medico de Chile which, after being permitted by the government to elect its own officers for the first time since 1972, embarked on a programme of medical ethical awareness, including the novel initiative of publishing, in November 1983, the WMA's Declaration of Tokyo as a paid advertisement in a major Santiago daily newspaper. This reflected the Colegio's belief in the importance of a public and professional understanding of ethical standards particularly with regard to torture. See, Stover E. *The Open Secret: Torture and the Medical Profession in Chile.* Wahsington: AAAS, 1987.

[21] Individual doctors can nevertheless speak out. The case of Dr Wendy Orr in South Africa is illuminating. On commencing work as a district surgeon in the Port Elizabeth area in 1985, she was struck by the number of prisoners alleging assault most of whom had injuries consistent with their allegations; she noted the complaints on the medical record cards, adding that these should be investigated. When her efforts to have some action taken on the persisting compalints of police brutality and torture had no effect she sought an urgent ruling from the Supreme Court restraining police from assaulting prisoners. An interim injuction was made. See Rayner M. *Turning a Blind Eye?* Washington: AAAS, 1987.

Steve Biko and South African Medical Community

mary rayner

Steve Biko a leading exponent of Black Consciousness was detained and tortured to death in September 1977 by the South African police. The doctors who were called in to examine the detained, although aware of the fact that he had been tortured failed to raise a protest. Nor did they ensure that the detainee was adequately cared for when at last he was moved to a hospital. Their role raised a controversy in the professional bodies in South Africa which has subsequently had an impact on the attitude and the functioning of these bodies and of individual doctors on the medical profession's ethics regarding the torture of prisoners.

The article is reproduced from Turning a Blind Eye? Medical Accountability and the Prevention of Torture in South Africa *by Mary Rayner, Committee on Scientific Freedom and Responsibility of American Association for the Advancement of Science, New York, 1987.*

EARLY on the morning of September 7, 1977, Dr. Ivor Lang, a Port Elizabeth district surgeon[1] was summoned by Col. Goosen, head of the security police in the Eastern Cape, to examine a detainee, Steve Biko. A leading exponent of Black Consciousness—the mixture of ideas and action which emerged in the early 1970s to unite black people against apartheid and white supremacy—Steve Biko had been held in detention under Section 6 of the Terrorism Act since August 19.[2] On the morning of September 6, the detainee had been taken from Walmer police station cells to security police headquarters for interrogation. At 7.30 a.m. on September 7, Major Snyman, leader of the day interrogation team, had reported to Col. Goosen that Biko was acting strangely and was refusing to react to questions. Col. Goosen asked Dr. Lang to examine the detainee for a suspected storke. In Goosen's presence Lang examined the detainee, who was lying on a mat, manacled to a metal grille in an office at security police headquarters.

During his examination, which was made at floor level, Dr. Lang found a laceration on the patient's upper lip which was edematous, a superficial bruise over the sternum at approximately the level of the second rib, a ring mark around each wrist, and edema of both hands, feet and ankles. The detainee also walked with an ataxic gait and spoke in a slurred manner. When asked by Col. Goosen for a medical certificate, Dr. Lang wrote:

> This is to certify that I have examined Steve Biko as a result of a request from Col. Goosen of the security police who complained that the above-mentioned would not speak. I have found no evidence of any abnormality or pathology on the patient.[3]

The next day Dr. Lang was summoned again. This time he examined the detainee in the company of his superior. Dr. Benjamin Tucker, the chief district surgeon for Port Elizabeth. The patient, still shackled to the grille, was lying on a mat now soaked with urine. During the examination, Dr. Tucker observed a possible extensor plantar reflecx in the patient,[4] who also complained of a pain in his head. Tucker and Lang contacted Dr. Hersch, a specialist in private practice, who agreed to examine Biko at Sydenham Prison Hospital. On September 9 Dr. Hersch performed a lumbar puncture, the results of which revealed bloodstaining in the cerebrospinal fluid. A neurosurgeon, Dr. Keeley, was consulted by phone. Although Keeley seemed not unduly worried regarding the patient's condition, he advised Dr. Lang to keep Biko under close observation.[5]

Apparently because the prison hospital had no observation facilities, Dr. Lang arranged for the patient to be transferred to the Walmar police station cells. As his final entry in the bed letter (medical record) at Sydenham Prison Hospital on September 10, Dr. Lang wrote: "No change in condition. Have informed him [Biko] that Dr. Hersch and myself find no pathology, that lumbar puncture was normal, and as a result I was returning him to the police cells."[6]

At the police station, the patient was left lying on a mat on the cement floor of the cell. Occasionally a police warden looked in on him. On the afternoor of September 11, Col. Goosen again called Dr. Tucker to the station. A police warden had found Biko collapsed, glassy-eyed, hyperventilating and frothing at the mouth. After a five-minute examination Dr. Tucker suggested that the patient be transferred to a provincial hospital in Port Elizabeth, but Col. Goosen refused to allow it. Tucker acquiesced in this and gave his permission to the police for the patient to be transferred by motor vehicle 750 miles to Pretoria.[7]

On the night of September 11 the semi-comatose patient, naked and handcuffed, was placed on some cell mats on the floor of a Land Rover and driven to Pretoria Central Prison. Biko was unaccompanied by any medical personnel during this long journey. No medical records on Biko's condition were sent with him. Several hours after his arrival at the prison Biko was examined by district surgeon Dr. A. Van Zyl. Without any information about the patient other than that he was refusing to eat, Dr. Van Zyl administered an intravenous drip and a vitamin injection. During the night of September 12, 1977, Steve Biko died lying on a floor mat and unattended.[8]

The Inquest

Three months later, spectator and reporters crowded daily into the large and ornate Old Synagogue building in Pretoria to hear the police and the doctors give evidence during the inquest into the death of Steve Biko. The proceedings attracted wide attention in South Africa and abroad, partly because of Steve Biko's political stature and also because of the notoriety gained by the police during the past year's student uprisings.

During the two weeks of evidence and intense cross-examination, the police witnesses were unable to explain the physical and mental deterioration Steve Biko underwent between the morning of September 6 when he entered the interrogation room and the morning of September 7 when he was first seen by a doctor. Their difficulty in providing a convincing explanation was dramatised when the counsel for Biko's family revealed in court a copy of a telex sent by Col. Goosen to police headquarters, in which he referred to an injury "which was inflicted on Mr. Biko at 0700 hours on September 7 after which he refused to speak".[9] The inquest magistrate, nonetheless, concluded that the likely cause of death was:

> Head injury with associated extensive brain injury, followed by contusion of the blood circulation, disseminated intravascular coagulation as well as renal failure with uraemia. The head injury was probably sustained during the morning of Wednesday, September 7, 1977, when the deceased was involved in a scuffle with member of the Security Branch of the South African Police at Port Elizabeth. Date of Death: September 12, 1977. The available evidence does not prove that the death was brought about by any act or omission involving or amounting to an offense on the part of any person.[10]

If the magistrate failed to use his power under the Inquest Act to draw conclusions concerning the culpability of the police, he did make an implicit judgment on the conduct of the medical practitioners who had attended to Steve Biko during the last week of his life. At the close of the inquest, the magistrate sent a portion of the inquest record containing the evidence of Drs. Lang, Tucker, and Hersch to the South African Medical and Dental Council. In so doing, the magistrate was acting in terms of Section 45 of the Medical, Dental, and Supplementary Health Service Professions Act of 1974, which provides that:

> Whenever in the course of any proceedings before any court of law it appears to the court that there is *prima facie* proof of improper or disgraceful conduct on the part of a registered person, or of conduct which, when regard is had to such person's profession, is improper or disgraceful, the court shall direct that a copy of the record of such proceedings, or such portion thereof as is material to the issue shall be transmitted to the South African Medical and Dental Council.[11]

During the inquest, the magistrate had received the advice and assistance of professors I. Gordon and J. A. Olivier, both pathologists of high reputation. Professor Gordon later stated that "at no time was there any doubt whatsoever in the mind of the presiding Judicial Officer or the two Medical Assessors, of whom I was one, that in terms of the Medical, Dental, and Health Professions Act...there was a *prima facie* case [of professional misconduct] against Dr. Lang and Dr. Tucker..."[12]

The results of the post mortem examination conducted by the Chief State Pathologist, Dr. J. O. Loubser, and the general autopsy performed by a neuropathologist, Professor N. S. F. Proctor, in the presence of two other leading pathologists including Dr. Jonathan Gluckman, were unequivocal in establishing that the cause of death was head injuries.[13] The inquest magistrate found that the injury which led to the patient's death was probably inflicted just prior to Dr. Lang's first visit at 9.30 a.m. on September 7, 1977. Photographs of the patient taken after his death clearly and unmistanably revealed a large scab on the patient's forehead.

All of this notwithstanding, Dr. Lang failed, apparently, to seen the injury on the forehead on the occasion of his first and subsequent examinations, according to a group of private South African doctors who submitted complaints to the South African Medical and Dental Council. Dr. Lang, they claimed, failed to attach any significance to the lip injury, or to other bruises and visible symptoms which Dr. Lang admitted in court having noticed. He failed to ask the patient for his account of how these injuries were sustained. He did not prescribe any treatment, carry out any routine blood or urine analysis tests, or take the patient's temperature at any stage. He did not recommend to the police that Biko should not be left lying on the floor or urine-soaked bedding. He failed to keep the patient under medical observation following Biko's transfer from Sydenham Prison Hospital to the Walmer police station. He did not keep Hersch and Keeley fully informed about the patient's condition or of actions taken which may have affected his condition. He failed to insist upon proper hospitalisation, or to oppose Dr. Tucker's acquiescence in the plan to send the patient to Pretoria. And only Steve Biko died did Dr Lang make any notes or reports of his findings.[14]

When counsel Sydney Kentridge pressed Dr. Lang during the inquest to explain his behaviour towards the patient, Lang stated that he believed the detainee was deliberately feigning illness. Col. Goosen had informed Lang that Biko had studied medicine for four years and that Biko had exhibited 'similar symptoms' during his previous period of detention. Lang claimed that Col. Goosen's comments had influenced his opinion. When questioned about his failure to ask Biko for his account of the lip injury and chest bruises, Lang stated that he had assumed they were sustained while the poilice were attempting to restrain the detainee, who, according to Col. Goosen, had gone into a rage on the morning of

September 7 and had attempted to assault an officer with a chair.[15]

On the issue of proper hospitalisation, Dr. Lang told the court that neither he nor Dr. Tucker had any option but to acquiesce in security police demands. Dr. Lang stated that he had the 'impression' that Mr. Biko could not be transferred to a non-prison hospital because he was regarded as "a security risk." Dr. Lang buttressed his defence by claiming that "we [district surgeons] are restricted in the sense that we cannot tell them where we wanted a detainee... You cannot buck the security branch."[16]

The effect of this particular line of defense was vitiated when Dr. Lang later admitted to the court that he had not really pressed the issue of hospitalisation with Col. Goosen. Goosen, Dr. Lang said, could have interpreted his reference to hospitalisation as necessary for diagnostic rather than treatment purposes. When asked if he at any stage suggested to Goosen that Biko was a sick man in need of treatment in a hospital, Dr. Lang acknowledged: "No, I did not."[17]

The two most egregious instances of questionable behaviour raised against Dr. Lang during the inquest concerned his medical certificate and his final entry in the bed letter. Col Goosen told the court that his request for a medical certificate on September 7 was 'plain logic'. Dr. Lang's certificate was, he added, completely satisfactory for his purposes. In the certificate. Dr. Lang had recorded as the reason for holding the medical examination that Biko "would not speak". Yet, in his later report to the pathologist conducting the post mortem, Dr. Lang wrote: "The detainee had refused water and food and displayed a weakness of all four limbs and it was feared that he had suffered a stroke." But, when asked to explain the discrepancy between these two statements, Dr. Lang could only reply: "I cannot explain it. It is inexplicable."[18]

In the second part of Dr. Lang's certificate of September 7, he noted that he had found no evidence of any abnormality or pathology. Dr. Lang admitted that this claim was "highly inaccurate" as he had found evidence of bruising, a lip injury, and edematous swelling of the hands, feet and ankles. Counsel Sydney Kentridge then asked Dr. Lang if it hadn't occurred to him that, "if, at some later stage, Biko might appear in court and complain about the way he was treated while in security police custody, [his] medical certificate would be a most important piece of evidence"? The doctor agreed that it would be but added that the possibility had not occurred to him on the morning of September 7.[19]

Dr. Lang had similar difficulty in explaining the contents of the entry in the Sydenham Prison Hospital bed letter, dated 10 September. He admitted that the statement regarding the lack of evidence of pathology was false. he knew that the cerebrospinal fluid was blood-stained, and that Dr. Hersch had reconfirmed the extensor plantar response. Nevertheless, Dr. Lang argued that the misstatement arose from the inadvertent omission of the word "gross" infron of "pathology".[20]

In his testimony, Dr. Tucker, the chief district surgeon in Port Elizabeth, attempted to explain his behaviour towards the patient, both claiming that he had accepted Col. Goosen's theory of feigned illness and by alluding to constraints affecting district surgeons' activities in relation to political detainees. At one point Professor Gorden pressed Dr. Tucker to explain why he did not tell Col. Goosen that he would disclaim all responsibility as a doctor if Biko was not taken to a proper hospital. Dr. Tucker replied that he did not consider the patient's condition as serious, as "there was still this question of a possible shamming on his [Biko's] part." He did concede, however, that no one could feign an extensor plantar reflex or red blood cells in the cerebrospinal fluid. he also accepted that, in terms of the Hippocratic Oath, the interests of his patients should always be paramount. But in this instance, Tucker admitted, as had Dr. Lang, that they were subordinated to the interests of security. "I didn't know," he said, "that in this particular situation one

Excert From the Inquest

Kentridge: Why didn't you stand up for the interests of your (Counsel for patient? Biko family)

Lang: I didn't know that in this particular situation one could override the decisions made by a responsible police officer.

Gordon: Why didn't you say that unless Biko goes to hospital you would wipe your hands of it?

Lang: I did not think at that stage that Biko's condition would become so serious. There was still the question of a possible shamming.

Kentridge: Did you think the plantar reflex could be feigned?

Lang: No.

Kentridge: Did you think a man could feign red blood cels in his cerebral spinal fluid?

Lang: No

Kentridge: In terms of the Hippocratic Oath are not the interests of your patients paramount?

Lang: Yes.

Kentridge: But in this instance they wer subordinated to the interests of security?

Lang: Yes.

(Inquest into the death of Steve Biko, Proceedings, in Bernstein, *Biko*, p. 94).

could override the decisions made by a responsible police officer."[21]

On several occasions during the inquest porceedings, Dr. Tucker contradicted himself. Although stating at one point his belief that Biko may have been feigning illness. Tucker claimed elsewhere in his evidence that the though of head injury had occurred to him. yet he failed to ask the detainee the source of his lip injury or the police if Biko had received a blow on the head. Dr. Tucker initially denied that his reticence came from dealing with the security plice. When Kentridge pressed him on this issue, however, Tucker reponded. "I would say no, you don't [ask questions in that situation]." After a five minute court adjournment, Dr. Tucker, in resuming his evidence, retracted his statement. "Questions asked by the district surgeon," he said, "are not banned in the security offices." He further claimed that, "at all times I have always had all the co-operation necessary from the security police. When we require information and when we require things to be done, then they are done."[22]

If Dr. Tucker's assertion about the co-operativeness of the police was correct, then it threw on onus of responsibility for the fatal pretoria journey directly on to his shoulders. Tucker's evidence shows that he deferred without protest to Col. Goosen's refusal to allow the detainee local hospitalisation. Dr. Tucker consented to Goosen's alternative proposal tht the patient be transported to Pretoria by motor vehicle. The only aspect the arrangements he claimed to have insisted upon was the need for a soft mattress. Tucker stated later, however, theat he neither saw it as his responsibility to check the vehicle used nor reassure himself that there was infact a mattress, blankets, and a pillow for the patient. Furthermore, he did not consider it part of his responsibility to insist that Biko be accompanied by a medical attendent or his medical records.[23]

On the crucial matter of the state of Steve Biko's health the day before his death, Dr. Tucker had written that he found no positive sign of organic disease and that the patent's condition was satisfactory. Under questioning Tucker admitted that he had found the patient lying on the floor with forth at his mouth and hyperventilating. He had found the patient weak in the left arm and apathetic. He admitted that he knew of the extensor plantar reflex. Nevertheless, when challenged to admit that "in this situation no honest doctor could have advised that Biko's condition was satisfactory," Dr. Tucker persisted. "In the circumstances, [I] though it was," he said.[24]

In his final submission made to the court on behalf of the Biko family, Counsel Sydney Kentridge strongly criticised the indifference displayed by Drs. Lang and Tucker towards the patient. Their relationship to Col. Goosen, he charged, "was one of subservience bordering on collusion." And their behaviour carried a significance beyond the present case. For "the medical profession's general reputation has led couts in the past, whenever an issue arose as to whether a prisoner seen by a doctor had been assaulted or not, to place great if not absolute reliance on the district surgeon's findings." Kentridge submitted that in this case "the proved facts show that not only can the court not rely on the evidence of Drs. Ivor Lang and Benjamin Tucker, but that an analysis of the evidence show that they joined with the security police in a conspiracy of silence." The very best that could be said, he argued, was that "they turned a blind eye." Kentridge concluded that the doctors' neglect of the patient's interests in deference to the requirements of the security police "was a breach of their professional duty, which may have contributed to the final result."[25]

Excert From the Inquest

Kentridge : Why did you not ask the obvious question, whether the man received a bump on the head?
Tucker : I did not ask it and that is all I can say.
Prins (magistrate) : Did you ask Biko?
Tucker : No.
Kentridge : Was it not possible you were reluctant to embarrass Goosen?
Tucker : No.
Kentridge : Either from reading about it or from your own experience have you no knowledge that the police assault people in custody?
Tucker : I have. (Further answer inaudible).
Kentridge : But on that occasion you did not ask?
Tucker : No, I did not. Where persons are brought to me for examination my report is completed on a special form. This is all I am required to do. This history was given to Dr. Lang... The restraint [on the morning of 7 September] could have resulted in the damage.
Kentridge : You accept it as a fact, what Goosen told you?
Tucker : May I put it this way? If am called to see a patient and he has a cut onhis head, then I am interested in treating him and not in how he got the cut.

(Inquest into the death of Steve Biko, Proceedings, in Bernstein, *Biko*, p. 85)

Response of South African Medical Dental Councils

The South African Medical and Dentral Council (hereafter referred to as the Medical and Dental Council) is South Africa's principal regulatory body controlling the medical and dental professions. The thirty-four member

statutory body has the power, under the 1974 Medical, Dental, and Supplementary Health Service Professions Act, to license and control the trainings of the members of the medical and dental professions and to uphold ethical medical standards. The Medical and Dental Council is vested with quasi-judicial powers to regulate the conduct of the medical and dental professions, including the authority to institute an inquiry into any complaint, charge, or allegation of improper or disgraceful conduct against any person licensed as a practitioner by the council. The Medical and Dental Council has the power to impose penalties, including striking the person off the register of licensed practitioners.[26]

The 1974 Act does not define improper or disgraceful conduct. The Medical and Dental Council has the discretion to define such conduct, and, periodically, the council makes rules specifying the acts and omissions for which it may take disciplinary steps against a registered member of the medical or dental professions. For instance, in 1976, the year prior to Steve Biko's death, the Minister of Health approved, *inter alia*, a rule prohibiting a practitioner from issuing a medical certificate unless he or she is satisfied from personal observation that the facts are correctly stated therein, or has qualified the certificate with the words "as I am informed by the patient."[27] In a 1985 Supreme Court review of the powers and duties of the Medical and Dental Council, the presiding judge described the council as "truly a statutory *custos morum* of the medical profession, the guardian of the prestige, status, and dignity of the profession and the public interest, in so far as members of the public are affected by the conduct of members of the profession . . ."[28]

Despite its clearly crucial disciplinary role, the Medical and Dental Council was to prove wholly inadequate for the task before it. In January 1978 the council received from Magistrate Prins a copy of the inquest proceedings involving Lang and Tucker's evidence. At the same time, the Medical and Dental Council was set a formal "complaint" by Mr. Eugene Roelofse, ombudsman for the South African Council of Churches. Mr. Roelofse's complaint posed a series of questions regarding the ethical conduct of Drs. Lang and Tucker.[29] Though Mr. Roelofse did not formulate specific charges against the physicians, the Medical and Dentral Council's president treated the matter as a complaint within the meaning of the Act. He directed the council registrar to refer the complaint, with the portion of the inquest record, to the council's Medical Committee of Preliminary Inquiry (hereafter referred to as the inquiry committee).[30] He also directed the registrar to send copies of these documents to Drs. Lang and Tucker and to ask them for an explanation.

In response the state attorney, acting on behalf of Drs. Lang and Tucker, requested a postponement of the inquiry, pending the outcome of civil proceedings launched by members of the Biko family.[31] When the Medical and Dental Council's registrar insisted on an explanation from the doctors, the state attorney replied that the complaint lacked the specificity necessary to initiate action by the inquiry committee and that it was defective in certain respects. The two doctors then applied to the Supreme Court for a ruling to this effect. The presiding judge dismissed the doctor's application.[32]

On April 24, 1980 the five-member inquiry committee met to consider the inquest record and other materials. The inquiry committee resolved that the contents of the documents be noted and, in a highly unusual move, the committee released its findings to the press before the full council had met to consider the resolution. In the *South African Medical Journal* of May 17, 1989, the inquiry committee announced that it had found no *prima facie* evidence of improper or disgraceful conduct on the part of the practitioners and that it had resolved that no further action be taken in the matter. Professor Gordon, one of the medical assessors at the inquest, later described this premature public release of the inquiry committee's findings as unprecedented in his 25 years of service as a council member.[33]

The Medical and Dental Council met on June 17, 1980 to consider the inquiry committee's resolution. At the meeting two members, Professors Shapiro and Carlton, attempted to convince the council that it should not confirm the inquiry committee's resolution; that there was *prima facie* evidence of improper or disgraceful conduct on the part of Drs. Lang and Tucker; and that a second inquiry into their conduct should be held.[34] Their motion was put to the vote and defeated. The resolution of the inquiry committee was confirmed by a majority of eighteen votes to nine.[35]

The Medical and Dental Council's decision provoked an uproar in the medical community.[36] The medical faculties of the Universities of Cape Town and the Witwatersrand disassociated themselves from the position adopted by the council. The Board of the Witwatersrand Medical Faculty in Johannesburg unanimously adopted a resolution expressing their deep disquiet at the council's finding. The Witwatersrand faculty felt that there was sufficient *prima facie* evidence to warrant a disciplinary hearing, and warned that "the South African Medical and Dental Council might have called into question its own credibility as an objective and unbiased guardian of the high standards of the medical profession in South Africa." In addition the medical faculty expressed concern as "to the possible effects of the decision of the Medical Council on the future treatment of prisoners and detainees by the authorities." The faculty went on to endorse the Guidelines for Medical Doctors Concerning Detainees and Prisoners, adopted by the World Medical Association (WMA) in Tokyo in 1975.[37]

The Witwatersrand medical faculty noted in its resolution that the Medical and Dental Council, as the purported watch-dog of the ethics of the profession, had been zealous, even over-zealous, in the severity of the punishments meted out in the past for even minor infringements of medical ethics. Yet, in the present case, they found it difficult to accept "that the council [had] applied its collective mind to the problem of the Biko doctors in a purely objective and dispassionate way."[38]

Despite these protests and the indications that medical associations in other countries were beginning to review their ties with South African medical organisations, the Medical and Dentral Council announced in October 1980 that its dismissal of the complaints against the Biko doctors was final and irreversible.[39]

The Medical and Dental Council's controversial decision forced critics to turn to the Medical Association of South Africa (MASA), a non-statutory professional organisation whose membership is purely voluntary.[40] On June 18, 1980 Dr. Jonathan Gluckman, a pathologist who had attended the post mortem on Biko on behalf of the deceased's family and a member of MASA's Federal Council, presented the association's secretary general, Dr. C. Viljoen, with a letter signed by 38 association members. The signatories called for an inquiry to determine whether Dr. Benjamin Tucker ". . . is a fit and proper person to continue to be a member of this Association." (Dr. Lang was not a member of MASA.)[41]

In accordance with MASA's Articles of Association, Dr. Wiljeon referred the letter with copies of a portion of the inquest record to the Cape Midlands Branch of the association where Dr. Tucker held membership. Unlike the Medical and Dentral Council, MASA lacked wide powers of inquiry and punishment. Its powers of censure over its members were limited to that of expulsion, with the initiative for this lying at the branch level and not at the national level. In this instance, the Cape Midlands Branch notified the MASA's Federal Council two weeks later "that a charge of unethical conduct against Dr. Tucker could not be sustained" and advised that "the case now be closed."

The executive committee of MASA's Federal Council met in August 1980 and accepted this recommendation. The committee also resolved that the findings of the Medical and Dental Council and its inquiry committee "be noted." Even so, the Federal Council's executive committee did raise questions concerning the conformity of the medical care received by Biko with the WMA guidelines in the Declaration of Tokyo. The executive committee acknowledged that the lack of conformity probably contributed to the "subsequent unfortunate course of events." Nevertheless, the executive committee shifted the focus of its questioning away from the conduct of the doctors to the possibly restrictive effects of existing laws and regulations upon doctors operating within the prisons.[42]

Two additional resolutions adopted by the Federal Council's executive committee alluded to the growing domestic and international controversy surrounding the response of the medical establishment to the charges against the Biko doctors. The committee defended the 'integrity and bona fides' of the members of the Medical and Dental Council and its inquiry committee, and MASA's Cape Midlands Branch. They also expressed MASA's satisfaction that the decisions of these bodies "had in no way been subject to outside influence and that there had not been any attempt at a 'cover-up' with regard to the conduct of the practitioners concerned."

In contrast, the Federal Council's executive committee viewed the critics of these bodies as proceeding on the basis of flawed newspaper reports, "which were frequently incomplete, biased, or based on political rather than ethical or humane considerations." The executive committee concluded that if evidence of improper or disgraceful conduct could not be found by the Medical and Dental Council's inquiry committee, the members of the MASA executive committee "could not be expected to submit to pressure or to violate their own consciences by laying a charge simply to satisfy the demands being made."[43]

To members of the South African medical community anxious to investigate fully the conduct of the Biko doctors, it appeared that the medical establishment had closed ranks. This impression was strengthened by statements published in September 1980 in the *South African Medical Journal*, the official journal of MASA.[44] The journal contained a statement by the Federal Council's executive committee recapitulating the discussion and resolutions passed at its August meeting. The chairman of the Federal Council, Dr. J. N. de Klerk, pointed out in the journal that three separate medical bodes independently had reached the same conclusion, namely, "that in light of the evidence available to them, and taking into consideration the particular circumstances surrounding this whole matter, the doctors were not guilty of negligence or of improper or disgraceful conduct." For those colleagues who still disagreed with these findings, de Klerk had only cold comfort. "Manifestly," he concluded, "the [Medical and Dental] Council itself is not able to reopen the matter, while the ethical committees of the MASA are substantially in agreement with its findings."[45]

MASA's stance provoked a spate of resignations among its members most prominently that of Professor Stuart Saunders, then principal-designate of the University of Cape Town, and Professor Frances Ames, head of the Department of Neurology at the same university. In a 'letter to the editor' of the *South African Medical Journal*, Professor Saunders challenged MASA's Federal Council to state openly the implications of its position: namely, that medical doctors should acquiesce in decisions taken by the police and accept that there are considerations other

than the patient's welfare to be taken into account in treating a prisoner. Professor Gordon, in announcing his decision not to stand for re-election for the executive committee of the Federal Council after 25 years of service, characterised the actions of the Medical and Dental Council and the MASA executive committee in exculpating the doctors as "an act of impertinence and arrogance."[46]

The resignations and negative publicity eventually produced a response from MASA's Federal Council. Dr. Jonathan Gulckman persuaded it to form a committee to inquire into the ethical issues raised by the medical treatment of Biko. The Federal Council also agreed to approach the government on the matter of the medical treatment of prisoners, especially those detained under the security laws, and to establish a code of conduct for medical practitioners working under these circumstances.

In a statement to the press announcing these decisions, Dr. Gluckman expressed his personal distress at the position adopted by the Medical and Dental Council. He acknowledged, as a member of MASA's Federal Council, "that mistakes have been made by us in MASA in the handling of the Biko matter." Dr. Gluckman said that it was essential "in the public interest and in the interests of the reputation and the good standing of the medical profession as well as in the interests of the prisoners that these mistakes be rectified."[47]

The Ad Hoc Committee appointed to consider certain ethical issues (hereafter referred to as the ad hoc committee) reported to MASA in June 1981. Investigations by the ad hoc committee were limited by its lack of subpoena powers and the fact that Dr. Lang and Dr. Tucker did not participate in any of the committee's proceedings.[48] In addition, the police denied the ad hoc committee permission to examine the Walmer police station cells where Steve Biko had been held. The ad hoc committee's report, however, critically reviewed the available evidence concerning the doctors' conduct and openly disagreed with the findings of the Medical and Dental Council.[49]

The report of the ad hoc committee encouraged those doctors who were dissatisfied with the Medical and Dental Council's decisions. Five doctors subsequently lodged with the council a detailed series of charges and complaints concerning the conduct of Drs. Lang. Tucker, Hersch, and Keeley. Appended to the document was a list of sixteen cases, dating from 1974 through 1980, involving similar instances of improper or disgraceful conduct by medical practitioners, along with the sentences imposed by the council's disciplinary committees.[50] A month later, in March 1982, five other doctors, together with the Transvaal Medical Society (now the Health Workers' Association), a voluntary organisation of mostly black doctors and allied personnel, lodged a separate list of complaints against Dr. Lang and Tucker.[51] Both sets of complainants referred extensively to the full record of the inquest proceedings in detailing and motivating the charges against the doctors.

In March 1983 the Medical and Dental Council's inquiry committee met to consider the allegations. The inquiry committee resolved "that all material evidence which had been submitted in support of the present complaint had also been considered by the committee and the council previously, and that no new material evidence had emerged such as warranted the rescission of the council's previous resolution". Accordingly the inquiry committee resolved that no further action should be taken against the doctors. A month later the Medical and Dental Council confirmed this resolution, once again rejecting a motion proposed by Drs. Shapiro and Carlton to the contrary.[52]

Faced with this rebuff, the complainants were forced to seek Supreme Court review of the matter. They petitioned the Court to set aside the resolutions of the Medical and Dental Council and its inquiry committee, and to direct the council to hold a new inquiry into the allegations of improper or disgraceful conduct on the part of Drs. Lang and Tucker. The petitioners argued that it was in the public interest and in the interest of South Africa that the applicants' complaint be properly heard. "The international reputation... of medical practitioners within the Republic," they noted, "has been tarnished by the fact that the [council] had failed properly to get to grips with an inquiry into the conduct of the medical practitioners whose conduct is in issue."[53]

In January 1985 the Court ruled in the petitioners' favor. It found that the inquest proceedings did support the charges and complaints of the applicants, and that there was *prima facie* evidence of improper or disgraceful conduct on the part of Drs. Lang and Tucker. The presiding judge referred, *inter alia*, to Dr. Lang's false medical certificate which represented an apparent breach of one of the Medical and Dental Council's rules of ethics. The inquiry council and its inquiry committee, in concluding otherwise, had misdirected themselves. The Court also found that the applicants, as medical practitioners, did have *locus standi* to approach the Court, because the purpose of the 1974 Act governing the activities of the council was intended not only to protect the public vis-a-vis the medical profession but also the reputation of the medical profession itself.

The Court then issued an order repudiating the resolutions adopted by the Medical and Dental Council and its inquiry committee in 1983. It directed the inquiry committee to resolve "that the evidence furnished in support of the aforementioned complaints discloses *prima facie* evidence of improper or disgraceful conduct, or conduct which when regard is had to the respective professions of [Drs. Lang and Tucker] is improper or disgraceful." It further directed the council to establish a disciplinary com-

mittee to investigate the conduct of the doctors.[54]

After seven years of evading its statutory responsibilities, the Medical and Dental Council was now forced to hold disciplinary proceedings against the doctors. In July 1985 a disciplinary committee, chaired by the president of the council, held hearings for four days. The committee found Dr. Lang guilty of improper conduct on 5 counts in that it (1) had issued an incorrect medical certificate and a misleading letter; (2) had failed to examine the patient properly; (3) had failed to inquire into and ascertain the possibilities of a head injury; (4) had failed to obtain a proper medical history of the patient; and (5) had failed to observe him and keep proper notes. Dr. Lang, who intended to continue practicing for a further five years, was given a caution and a reprimand.

The disciplinary committee found Dr. Tucker guilty of improper and disgraceful conduct on 3 counts: (1) he had failed to object to the patient's transportation by a Land Rover to Pretoria; (2) he should have insisted upon transportation by ambulance with proper medical attendants and the patient's medical records; and (3) he failed to make a proper medical check before stating that the patient's central nervous system had shown changes between examinations. The committee suspended Dr. Tucker, who was due to retire shortly, for three months from the medical rolls, but recommended that the enactment of the penalty should be suspended for two years conditional on his not being found guilty by the council or any other contravention during this period.

MASA's secretary general Dr. Viljoen issued a statement welcoming the committee's judgment. Dr. Viljoen added that "as in the past the findings of the Medical and Dental Council were accepted by the MASA." The sentences, however, were strongly criticised by others as being "pathetically inadequate." Several months later, in October 1985, the council stripped Dr. Tucker of his medical qualifications.[55]

The failure of the Medical and Dental Council and MASA to respond quickly and appropriately to the allegations against the Biko doctors had resulted in a bitter international controversy concerning MASA's membership within the World Medical Association. In 1981 a number of national medical associations, including the British Medical Association, withdrew from the world body in protest over MASA's continuing membership. Throughout 1985, international pressure on the WMA, combined with a campaign inside South Africa by a broad range of medical and health groups, led the WMA to alter its plans to hold its next annual meeting in Cape Town.[56]

Amid this controversy over its international standing, MASA acknowledged that the "Biko case" had done irreparable harm to the South African medical profession. The association, however, maintains a defensive posture on the matter in its correspondence in professional journals, which has only deepened the growing polarisation within the South Africa medical community. During an interview in 1985, Professor Frances Ames, one of the petitioners in the Supreme Court case against the Medical and Dental Council, expressed her concern about "this polarisation amongst medical doctors." The formation of an alternative professional association, the National Medical and Dental Association (NAMDA), in 1982 concretely expressed the dissension within the medical community.[57]

During part of an exchange with MASA on ethical issues which was published in the *South African Journal of Human Rights*, Professor Trefor Jenkins, one of the applicants in the Supreme Court suit, urged MASA to admit that it had made errors of judgment in the Biko case. Professor Jenkins argued that doctors, like other members of the society, have been initimidated by the police and the repressive measures used to implement and maintain *apartheid*. It was his firm belief that "the Council (and to some extent the MASA) [had] allowed itself to be influenced by irrelevant considerations when discussing the case of the Biko doctors." The case was, he felt, "one of straightforward and relatively simple medical ethics but the two bodies in question [had] allowed political (and, perhaps, what they perceived to be state security) considerations to cloud the issue." No good would be served, he said, by MASA persisting in the view that it did all it possibly could to ensure that justice was done in dealing with the unprofessional and even disgraceful conduct of the doctors who cared for Biko." Professor Jenkins suggested that MASA intensify its efforts to restore the image of the profession to one in which all doctors could feel proud and in which the public could feel confidence again. In a situation of deepening conflict in the country, the medical profession, Professor Jenkins urged, must be prepared to censure unequivocally any doctor who fails to expose police brutality or torture, lest irreparable harm be done to the trust relationship existing between doctor and patient, and the practice of medicine become impossible.[58]

Notes

1 District surgeons and general practitioners employed by the Department of Health. Their responsibilities include the provision of medical care to prisoners under regulation 6 of the prison regulations promulgated in 1965 under Prisons Act 8 of 1959. About 26 localities in South Africa have full time district surgeons. Part-time district surgeons operate elsewhere. Interview with Mr. Filmalter, acting registrar of the South African Medical and Dental Council, by Eric Stover in Pretoria in December 1985; Gilbert Marcus, "Safeguarding the Health of Detainees," unpublished paper, Center for Applied Legal Studies, University of the Witwatersrand, April 1987, pp 6-9.

2 Biko had been detained on a number of occasions, including for a period of 137 days in 1975. He had also been subjected

to a five-year banning order. Concerning his life and political activities, see Hilda Bernstein, *No 46—Steve Biko* (London: International Defense and Aid Fund, 1978); Milard Arnold, ed, *Steve Biko, Black Consciousness in South Africa* (New York: Vintage Books, 1979); Gail M Gerhart, *Black Power in South Africa: The Evolution of an Ideology* (Berkeley: Unversity of California Press, 1978).

30 The inquiry committee, created under Section 61(1)(a) of the 1974 Act, is appointed at the beginning of each year from the members of the Medical and Dental Council and is charged with the duty of conducting a preliminary inquiry into complaints.

31 The plaintiffs brought an action for R90,000 damages against the security police, Drs. Lang and Tucker, and the Ministers of Health and Police. In July the Biko family accepted an out-of-court settlement of R65,000 from the State. The Minister of Police denied that the settlement amountd to an admission of liability. Lawyers' Committee for Civil Rights under Law, *Deaths in Detention*, pp 67-68.

32 Judgment in *Tucker & Another v. South African Medical and Dental Council & Others*,, 1980(2) SA 207 (TPD), pp 298, 213; Baxter, "Doctors on Trial," p 151. Judgment was rendered in December 1979.

33 *The Cape Times*, November 26, 1980; *Veriava*, p 299.

34 Quoted in *Veriava*, p 299.

35 Professor Gordon withdrew from the proceedings because of his involvement in the inquest. A number of other council members were absent when the final vote was taken. *Veriava*, p 299; Baxter, "Doctors on Trial," p 142.

36 Interview with Professor Phillip Tobias by Eric Stover in Johannesburg on December 11, 1985.

37 Reported in *Nature*, Vol 286, No 5770 (July 1980), p 200; *The Lancet*, No 8205 (November 29, 1980), pp 1184-1185. See Appendix A for Declaration of Tokyo text.

38 Reported in *Nature* (July 17, 1989); Trefor Jenkins, "The MASA Letter: A Rejoinder, The Organised Medical Profession on Trial," *South African Journal on Human Rights*, Vol 2, Pt. 2 (July 1986), p 236; "Biko Saga: The Ethics of Suppression," in *Critical Health* (Johannesburg), No 3 (July 1980), p 48; *Survey of Race Relations 1980* (Johannesburg: SAIRA, 1981), pp 570-572. In contrast to its response to the charge against the Biko doctors, the Medical and Dental Council moved quickly to organise disciplinary proceedings against Dr. Aubrey Mokoape, after he had served six years in prison for contravening the 1967 Terrorism Act. According to Amnesty International, Dr. Mokoape was interrogated, beaten, and held in solitary confinement during his

detention in 1974. He was convicted of two counts under the Terrosim Act, after a long trial in which the State attempted to prove a link between the Black Consciousness movement and political violence. Not a single act of violence was proved against any of the defendants. Two years after his release from prison Dr. Mokoape was informed that the Council's Medical Committee of Preliminary Inquiry had resolved that there was a *prima facie* case of improper or disgraceful conduct against him. The charge against him, relating solely to his conviction under the 1967 Act, represented the first occasion in which the council used a political conviction as ground for a disciplinary inquiry. One of the applicants in the Supreme Court suit initiated in 1984 against the council and the Biko doctors. Dr. Yosuf Veriava, attended the initial council hearing which he later described as making the council appear to be "an extension of the South African repressive machinery." The council eventually dropped the case after Dr. Mokoape's lawyers challenged the proceedings on technical grounds. Amnesty International, *Political Imprisonment in South Africa*, pp 59-60; summons issued against Dr. Mokoape by Mr. N. M. Prinsloo, Council Registrar, November 6, 1984; *Sunday Express*, January 13, 1985; *Sunday Tribune*, January 13, 1985; interview with Dr. Jerry Coovadia by author in Washington, D.C. on June 23, 1987.

39 *The Argus* (Cape Town), October 1, 1980.

40 According to Dr. Stuart Saunders of the University of Cape Town, about 70 per cent of the country's medical doctors are members of MASA. Dr. Jonathan Gluckman put the membership of MASA at between 10,00 and 11,000. Interview with Dr. Stuart Saunders by Eric Stover in Cape Town on December 14, 1985; interview with Dr. Jonathan Gluckman by Eric Stover in Johannesburg on December 9, 1985. Of 16,815 medical doctors in South Africa in 1983, 15,251 were white, 60 2343 'colored', 1,255 were Indian, and 249 were African (Department of Manpower figures for April 1983, quoted in Dr. M. Ramphele, 'Health and Social Welfare in South Africa Today', unpublished paper presented at AAAS annual meeting, Philadelphia, May 25, 1986, p 6).

41 Baxter, 'Doctors on Trial', p 142; private correspondence, Dr. Viljoen to Prof. S. J. Saunders, November 27, 1980.

42 Private correspondence, Dr. Viljoen to Prof. S. J. Saunders, November 26, 1980; Report to the Medical Association of South Africa, 1981, pp 7-8; *South Arican Medical Journal* (September 13, 1980), p 433.

43 Statement by the executive committee of the Federal Council, MASA, regarding the conduct of the doctors responsible for the treatment of the late Mr. S. B. Biko, in *South African Medical Journal*, (September 13, 1980), p 433.

45 The chairman of MASA's Federal Council, Prof. J. N. de Klerk, described the *SAMJ* as the "official organ and mouthpiece of MASA" which "must reflect the Association's policies," in a letter to Professor Stuart Saunders, November 27, 1980.

45 *South African Medical Journal*, (September 13, 1980), pp 432-433.

46 Letter to the editor of the *South African Medical Journal*, (September 17, 1980). Professor Saunder's letter was neither published nor acknowledged by the editor, although it appeared in full, without author's permission, as an agenda document for the Federal Council meeting of November 12, 1980. Private correspondence, Prof. Saunders to chairman of the Federal Council of MASA, November 14, 1980. Complaint lodged by Dr. Frances Ames and others, Annexure C. Apparently the journal editors also refused to publish the Witwatersrand Medical School statement on the case. Interview with Prof. Phillip Tobias by Eric Stover in Johannesburg on December 11, 1985. In the interview, Prof. Tobias criticised the then leadership of MASA for "dragging its heels in subservience to the government."

47 Press statement by Dr. Jonathan Gluckman, November 19, 1980.

48 The authors of the ad hoc committee report claimed that the Deputy Director of Health Services forbade the doctors' involvement in the proceedings. The Assistant Secretary of Health Services, according to Prof. Saunders, argued "why should my district surgeons take up rap for the police." Interview with Professor Stuart Saunders by Eric Stover in Cape Town on December 14, 1985.

40 Report to the Medical Association of South Africa by the Ad Hoc Committee appointed to consider certain ethical issues, June 1981; Baxter, 'Doctors on Trial', p 142.

50 Complaint by Dr. Frances Ames and others (see note 39). The complainants were Dr. Frances Ames; Dr. Edward Barker, senior surgeon, University of Natal Medical School; Dr. Trefor Jenkins, head of the Department of Human Genetics at the University of the Witwatersrand; Dr. Leslie Robertson, a medical general practitioner; and Dr. Phillip Tobias, dean of the Faculty of Medicine at the University of the Witwatersrand. Baxter, 'Doctors on Trial,' p 142; *Veriava*, p 299.

51 Complaint by the Transvaal Medical Society and others (see note 37). The individual complainants were Dr. Dumisani Mzamane, head of the Renal Unit at Baragwanath Hospital; Dr. Yosuf Veriava, a senior physician at Coronation Hospital; Dr. Rasik Gopal, neurosurgical registrar at Baragwanath Hospital; Dr. T Wilson, a pediatrician; and Dr. E. Holland. *Veriava*, p 30.

52 Baxter, 'Doctors on Trial', p 143; *Veriava*, pp 301-303.

53 Court papers in *Veriava*; Baxter, 'Doctors on Trial', p 143.

54 *Veriava*, pp 311-318.

55 Baxter, 'Doctors on Trial', pp 150-151; *South African Medical Journal*, Vol 63 (August 3, 1985) p 131; *The Lancet*, No 8447 (July 20, 1985), p 136; *The New York Times*, July 6, 1985; *The New York Times*, October 17, 1985.

In Defence of Civil Rights

A Biographical Sketch of Dr Ramanadhan

A doctor who renders help to political activists often comes into conflict with oppressive state apparatus and is himself a target of repression. Dr Ramanadhan's life and death exemplifies this. He was a civil liberties' activist, a human and rational doctor's who fell to a police bullet in Warangal in September 1985. This sketch is reprinted from an anniversary tribute to him published by the P U D R New Delhi.

MUSTIKUNTALA is a village in Mahira taluq, Khamamam district that separates the Telengana from the Andhra region. In the thirties the village had a small population of about three hundred, subsisting on cultivation of dry and barren land. But now the village has become prosperous thanks to canal irrigation and even has a high school.

It was in the village that Dr. Ramanadhan was born on October 16, 1933, third son of Anatarama Rao and Rajyalaxmi. The family had about 30 acres of dry jowar land. Ramanadhan was the first person in the family to insist on higher education and had to struggle his way to become a doctor. He completed his primary education in the village and did his secondary school is nearby Khammam. Despite family oppostion he went to C.R. Reddy College, Eluru for his intermediate, and then to the famous Nizam College, Hyderabad, for his B Sc. degree. During his Nizam College days he become part of a group of students who were peripherally associated with the All Hyderabad Students Union. The house of Dr. Balachandra Paranjpaye, well-known veteran of the Telengana struggle, was the cenre for all young men in those days. Dr. Paranjpaye remained a source of guidance to Ramanadhan all his life.

After his B.Sc he took up a number of irregular jobs for more than a year, which included teaching and a job as a medical representative. Around this time he also got married. Then he got admission in M.B.B.S. in the newly-established Gandhi Medical College, Hyderabad. Financially, these were his bad days, having to live on the limited amount sent by father and his house surgeonship. He joined Osmania College for his Diploma in Child Health. It was during this period that he became a student of the famous left wing intellecual, Dr. Rajagopalan. Both were to work together, twenty years later, in the APCLC. Throughout his student career he remained on the periphery of then student movement. In fact, later on too he never became part of any organised political group.

After completing his studies he joined government service. First he taught in Kakatiya Medical College and worked in Mahatma Gandhi Memorial Hospital where he was to die later. Then for over four years he worked in the listless primary health centers at Chityala, Vangara and Husnabad in the Warangal and Khammam districts. Primary health centres then and now are private clinics for those who weild social power in the village and not clinics for the people. Invariably Ramanadhan could not adjust himself to work in this kind of framework. Husnabad became his last job.

Husnabad, a taluq centre, is a big village with around a population of 10,000. If Health Centre serves a number of the neighbouring villages. The earlier doctors and compounders had established a routine pattern of corruption. They did not attend the centre, but used the medicines and equipment of the centre to run their own private clinics. When Ramanadhan took charge, he put an end to this practice. This earned him the warth of the compounder, the Block Development Officer, and the Samiti president who all used to share the booty. But Ramanadhan struggled against these forces and became a very popular doctor. Eventually things came to a head when he was asked to issue a death certificate for an unidentified young girl in the house of the Samiti president. The doctor refused. And soon after, he resigned from government service.

He set up his own children's clinic on Jayaprakash Narayan Road, Warangal, in 1968. He was the first pediatrician in the town and soon became very popular. It was from this period that he consciously engaged himself in social activities outside his profession.

In the early seventies, before the APCLC was formed, he became a kind of supportive centre for a number of people involved in a variety of problems and issues. He helped his friends run a monthly that became a well known non-commercial journal in Telegu, *Srjana*. In fact, be it a writers' organisation wanting to hold its first meeting in Warangal or a young couple facing family opposition to their marriage every one sought his help and received it. In a dramatic incident he rescued a young girl and conducted her marriage. The girl's parents were influential people with powerfull connections. In the midst of the marriage function, the police arrived and arrested the bridegroom and his friends, on charges of abduction. Eventually the girl won her battle in court.

In early 1974, along with another well-known doctor of Warangal, Dr. Amjad Ali Khan, he became a founder member of APCLC in Warangal. Around the same time, he also organised a polyclinic in Warangal. When emergency was declared in 1975 all activities ceased. The General Secretary of the APCLC, advocate Prattipati Venketewarli was among the first to be arrested. Ramanadhan was also arrested, which led to the closure of the people's clinic, virtually the only democratic activity in the town at that time. He was taken to the illegal camp

maintained by the police at Pakala reserve forest.

Pakala is a wild life sanctuary where two bungalows meant for tourists were turned into police camps during the emergency. A number of young people arrested during the emergency were detained here and tortured. Among them was the sole eye-witness to the Girapalli encounters in which four young men were shot dead in cold blood by the police. Dr. Ramanadhan, who was a fellow detainee of the eyewitness, as to be of crucial assistance to the Tarkunde Committee which brought out its famous report on these encounters after the emergency. He was shifted after three weeks detention at the Pakala camp to Warangal Central Prison, which serves as the main prison for five north-western district of Telengana.

After the lifting of emergency, the central government appointed the Shah Commission of Enquiry which managed to submit its report, although no action was taken on it. But anyone who has gone through the reports of the Commission can see that the largest number of crucial affidavits to the Commission from Andhra came from the Warangal region. Again, the aborted Bhargava Commission, which was appointed to enquire into encounter killings in Andhra, was helped by the mobilisation of crucial witnesses. In both instances, Dr. Ramanadhan played an unobtrusive but significance role.

In November 1977, a tidal wave hit Divi Seema in the Krishna district on the east coast. It led to hundreds of villages being marooned and to the death of thousands of people. Ramanadhan and his team was the first team of doctors to enter the inundated areas, before any government organisations or voluntary agencies. Later the team came back, raised funds, medicines and material necessities and went back to the flood affected areas and held a mobile medical camp for a month.

In late 1979, the junior doctors in Warangal along with their colleagues in the rest of the state went on a strike for over seventy days. The government attempted to suppress the strike at one level by repression and at another level by generating a mass hysteria against the striking doctors. Dr. Ramanadhan took the initiative and organsied a people's clinic opposite to the government hospital with the help of the doctors on strike. The clinic became a centre for both the medical service and the strike. The ramshackle pandal outside the hospital became so popular that poor people requested the dcotors to continue the clinic even after the eventual withdrawal of the strike.

In an unusual incident, Dr. Ramanadhan assited a Brahmin widow whose husband had been the priest of a temple. After his death the widow managed the temple. But the trustes rejected her, presumably because of the land value of the temple, on the ground that a woman cannot be a priest. APCLC Warangal, under Ramanadhan, took up her case and eventually won the battle for her and also set a precedent.

What earned him the wrath of the Warangal police was systematic efforts by the APCLC to expose the lawlessness of the police. Hundreds of illegal arrests, torture, setting up of armed police camps in villages and colleges alike have become routine in past years. Since 1983 at least 12 people were killed in either police lock-up or in so-called encounters. In Warangal district, the APCLC investigated each of these instances and brought police violence to the notice of the public. In a number of cases it provided legal help to the victims of police harrassment. It challenged the constitutional validity of the armed camps in the colleges and villages of Warangal. As the APCLC steppted up its campaign, it has become a fetter on the arbitrary behaviour of the Warrangal police establishment.

Initially the police began with a systematic campaign that APCLC was a extremist front organisation. APCLC's own diversified activities was projectd as an organisation that is working in the interests of extremists. Later, APCLC activities began to be implicated in false cases. In 1984, two of the activists were implicated in a case of obstructing police from discharging their duty. The case was later dismissed.

In January 1985, Dr. Ramanadhan was arrested along with Dr. K. Balagopal and K. Seetarama Rao. They were charged with, among other things, distributing arms to the extremists. The doctor was released on bail a week later. While he was in police lock-up, in a telling incident, the policemen who had arrested him brought his child for treatment to the doctor. The incident indicates the extent to which he had become popular, even among the policemen of Warangal.

Dr. Ramanadhan's social awareness helped him to understand the social origins of the diseaes of his patients. He did not confine himself to giving medicines but tried to spread a scientific outlook. It was in this process that he wrote the famous book *Medical Guide* (in Telugu) which was addressed to the people and not to the health workers. The book became very popular. A second edition came out within an year and now, after his death, a third edition has been printed. Even after establishing himself as a popular doctor, his interests in studies remained. He took part in different seminars and meetings of the profession. A few weeks before his death he participated in a conference held at Nizam Orthopedics Institute. This professionalism was to remain with him till the very end. In the last twenty minutes of his life en route to the hospital, he kept discussing with the young doctor, who took him in his car, the diagnosis of his injuries and suggesting treatment.

In a sense his involvement with his profession helped the civil rights movement which in turn made him a better doctor. He was a doctor not only to rickshaw pullers, hawkers, and slum-dwellers but also to the policemen and their children. A few days before his death, an SI who

was leaving the town on promotion came to him and gave him sweets by way of farewell. The SI is believed to have said that for Warangal police he is not only a civil rights activists but also a doctor. Ramanadhan accepted the sweets with the confidence in human relationships which he had built over sixteen years of service to his patients and to the people of Warangal. Evidently the policemen who killed him did not share such values.

But perhaps his patients, people for whose lives he had fought and whose rights he had defended shared them. That is why on September 4, defying Section 144 and undeterred by the presence of armed police, they came in their thousands and paid their respects to the man who fought for them. His life and death will remain a defiant celebration of human values and a never ending source of inspiration for the democratic movement.

Aftermath

The news of Dr. Ramanadhan's death reached Delhi on the morning of September 14, 1985. Two prominent Delhi dailies carried a report, field by a national news agency, that Dr. Ramanadhan, vice president of the APCLC was killed by 'extremists' in his clinic on the previous day. In fact no correspondents of this news agency, which does not have a Warangal office, were present in Warangal on September.3. The report was filed from Hyderabad, within two hours of the incident. All other stae-level and local dailies carried reports by their Warangal correspondents saying that the doctor was killed by armed policemen accompanying the dead body of SI Yadagiri Reddy.

Next day, the superintendent of police, Warangal, contradicated the local newspaper accounts and stated that Dr. Ramanadhan was possibly killed by some extremists. When eye-witness journalists pointed out that uniformed policemen were seen entering Dr. Ramanadhan's clinic, he stated that they had gone to the rescue of the doctor. On the same day, Vasant Nageswara Rao, home minister, made a statement on the incident in response to a notice under rule 329, tabled by 23 memebrs in the state assembly. The home minister maintained that the sugges tion that the police were behind the incident was 'baseless'. He added that the incident took place long after the funeral procession of armed police had left the place. He also indicated the involvement of extremists factions in the murder. Meanwhile APCLC had released its own report on the incident.

The postmortem report, quoted by the APCLC, states that the death was caused by a service revolver fired at point blank range. On that basis and other corroborative evidence APCLC demanded the immediate susupension of the senior police officials and ordering of a judicial enquiry. The government refused to hold a judicial enquiry. Instead a CBI CID enquiry was ordered. A few weeks later the government suddenly discovered that two policemen were guilty of dereliction of duty. They had let their service revolvers be stolen from them two months prior to the incident! Presumably the stolen revolvers were to be traced to the 'extremists' who somehow became part of an armed police procession and killed the doctor without anyone ever noticing it.

Meanwhile police claimed to have identified the six people who were involved in the Yadagiri Reddy murder case. The case itself was brought under the Terrorist and Disruptive Activities (Prevention) Act, 1985 which came into effect in Andhra Pradesh from August, 1985. This was the first and the only murder case so far under the act in the state. Two of the accused, Nageswara Rao and Ramakrishna, were killed in a so-called encounter in April this year. The other accused include Dr. K. Balagopal general secretary, APCLC, who was let out on bail and Dr. P. Varavara Rao, general secretary of the Revolutionary Writers Association, who is still in jail.

Eventually the CB CID enquiry did take place An SP who was till recently in the Andhra police was deputed for the enquiry. He visited Warangal in late October for three days and submitted the report to the government. It has not been released to the public or even to the assembly so far. But we understand that the report came to the conclusion that the "assailants remain unidentified".

Why Are Torturers Never Punished?

Case of Archana Guha

peter vesti

Archana Guha was arrested in July 1974 and subjected to 27 days of torture in the hands of the police. She was not charged formally but was made to believe that the arrest was because of her association with the Naxalite movement. After her release a physically shattered Archana filed a case against her torturers which has yet to be decided upon. This article was first published in the Danish Medical Bulletin, *1988.*

UNTIL recently, little was known about the various aspects of symptomatology or about treatment of torture victims. At the Rehabilitation Centre for Torture Victims in Copenhagen (RCT), over the past five years we have treated torture victims and compiled information about the essential aspects of treatment of these most unfortunate human beings.

These experiences have made it increasingly clear that the end-purpose of torture is to 'break' the person, i.e. to transform a formerly healthy member of society into an individual broken in spirit and unable to function efficiently in any aspect of personal or public life. An appalling insight by the torture victims is that the vast majority of people are indifferent about what has happened to them; even more horrifying is the undrstanding that the torturers continue to perform whatever duties they are assigned (perhaps including torture) and are never brought to justice, often in spite of a change of national regime or the election of new political parties.

This has been seen in various places and at various times in the world. International attention has focused on the very limited trials of only a few of the accused torturers in Greece after the fall of the military government [1], the strange circumstances surrounding the death of Steve Biko in South Africa [2], and the impotence of the newly elected government in Argentina to deal with criminals who were torturers under the former military junta [3].

A case that will illustrate such occurrences is the story of Archana.

In 1980, an Indian national by the name of Archana Guha was flown to Copenhagen to receive treatment at Rigshospitalet, one of our University Hospitals. Thrity-nine years old, she arrived on a stretcher, had years before been tourtured, and was now suffering the consequences. With the help of Amnesty International, she was transferred to Denmark to receive treatment at the centre later to be developed into the Rehabilitation Centre for Torture Victims (RCT). Following is a review of the circumstances of the case and the sad recognition that now, many years later, Archana's case against her tortures is still pending before the court in Calcutta.

The early 1970s were a violent time in West Bengal. A militant Marxist grouop, the Naxalities, were ravaging the countryside, and many people were caught inthe crossfire between it and a government using all means to fight it. One such person was Archana Guha. Educated as a school teacher, in 1967 she was appointed. head mistress of Kolorah Girls Junior High School outside Calcutta.

Arrest and Torture

On July 17, 1974, Archana was arrested in the middle of the night together with her sister-in-law and a friend staying in the house. No formal charges were brought against them, but they were made to believe that their arrests were due to some connection with the Naxalite movement. The matter was never brought to court.

Twenty-seven days of torture followed at Lalbazar, headquarters. of the Calcutta police. First, Archana was made to witness the assault on and torture of her sister-in law and her friend. She was then tied, hands and feet, slung upon a pole, head down, and severely beaten on the feet (falanga). The five policemen involved took turns hitting her and kicking her on the hips, and later they burned her toenails with cigars. She was threatened with rape and made to understand that her family would also be tortured if she did not cooperate. When she was not in the torture chamber, she was kept in a small, dark isolation cell. During the torture she was forced to sign several blank papers. She was suspended by her hair and, later, 'brain washed'—a term used by torturers for a procedure in which they begin a movement to bang her head against the wall, but at the very last moment before her head struck the wall, pull her back.This was done 10-20 times.

It seems likely that the three women were arrested because of Archana's brother Saumen. He was also accused of involvement with the Naxalite movement. He was arrested on the August 6, 1975, and when Archana's torturers learned of his arrest, they stopped torturing her. Saumen, himself, was allegedly on two occasions subjected to torture for periods of six and 14 days.

Archana never came before a judge, even though the law specifically states that this must take place within 24 hours of the arrest. On August 13,1974, Archana was brought to the Presidency Jail In September 1974 she was released, but immediately after was again detained under the Maintenance of Internal Security Act (MISA). She was

released on parole in November 1976 and on May 3, 1977 was also released from MISA detention. The Left Front (a coalition of left wing parties) was now in power in West Bengal.

After the torture, Archana had multiple symptoms. She suffered headache, swelling around the left eye, a burning sensation in the head, difficulty breathing, irregular periods as well as bleeding from the rectum. She suffered several infections in the urogenital system. She also suffered difficultly sleeping, had no appetite, and poor concentration.

Her condition deteriorated, and gradually she lost muscle strength in her arms and legs, grew weak and also lost sensation. She was confined to bed and to a wheelchair. From December 1975 to February 1976, she was hospitalised in the SSKM Hospital—was under round-the-clock police guard—but did not improve. She was later transfererred to the Medical College Hospital, still under police guard, still paralysed, and was told that she could expect no major improvement. An X-ray at that time showed a fracture of the seventh cervical vertebra.

Upon arrival in Denmark four or five years later, Archana was still suffering from a number of symptoms. She had constant headache, nausea, and muscualar pain in the neck and shoulders. She was constipated and slept poorly, suffered tremous, and was still unable to concentrate. She was mostly confined to bed, being unable to walk without human support.

Neurological examination showed a decrease in strength in the arms which were also somewhat atrophic. Her legs showed a decrease in strength bilaterally, both for flexion and for extension. Both legs were atrophic. The patient was unable to walk unless supported by two persons. The reflexes could not be elicited.

Examination of the skin revealed several scars and pigmentation changes compatible with the history of combustion and subsequent ulceration. The size of the scars were in accordance with the size of a scar caused by the glow of a small cigar. The patient also described pustulations and alopecia as well as discoloration after being suspended by her hair. This is also in accordance with known sequelae to traction alopecia.

Beyond doubt, most of the patient's symptoms and signs are the result of torture. It is equally clear that poor conditions in the prison (possibly a deficiency in protein) as well as the depressing effect of prison conditions in general and uncertainty about the future, sustained and possibly aggravated Archana's condition.

In August 1977, soon after she was released, Archana filed a petition accusing five policemen of having violated relevant sections of the Indian Penal Code. At that time, she was unable to walk and had to be carried to the courtroom to make a personal appearance. The accused were: Ranjiit Guha Neogi (Runu), officer in-charge of the investigation; Santosh De; Aditya Karriaka; Arun Banerjee; and Kamal Das, alias 'the golden hand', known for being able to make most people talk under torutre.

Archana also requested a reasonable compensation for almost three years in jail and was offered a few hundred rupees. The authorities would not even bear the expenses for her treatment at a major private clinic in Calcutta. With the help of Amnesty International and human rights groups as well as women's groups in India, attention was focused onthe case. Finally, the government in West Bengal agreed to pay the expenses involved in transferring Archana to Rigshospitalet in Copenhagen.

After intensive treatment, rehabilitation, and physiotherapy, Archana's health improved and gradually she was able to walk again. She later returned to India. While under treatment, she became painfully aware that her torturers in no way were affected by her petition and that the authorities apparently did not believe her and wanted the whole thing to be forgotton. We believe this influenced her rehabilitation negatively. During her stay in Denmark, she had made the acquaintance of an employee at Rigshospitalet, and Archana later moved back to Copenhagen to settle permanantly.

And what happened about the court case submitted in August 1977? Nothing much, I regret to say. None of the accused officers have been suspended. Death certificates have been produced for two of the accused (Aditya and Arun). Kamal Das (the golden hand) has disappeared and records seem not to indicate that he was employed by the Calcutta police in the first place. Every legal loophole has been used and abused to prolong the proceedings at the court. The accused have claimed that Archana's lawyer (A. P. Chatterjee) could not represent Archana because he was also the government's standing council. This was put to the high court as well as the Supreme Court twice before the legitimacy of his representing the client was confirmed. It appears that the evidence was misrepresented and the court misled the first time.

During the 1980s several human rights organisations and women's organisations followed the case and even demonstrated outside the court room—not for a verdict of guilt, but only for a speedy trial. Because of this, the accused filed a petition asking that these organisations be tried for contempt of court and that reportage of the trial be prohibited. The local magistrate did bar the newspapers from publishing the evidence of the witnesses. However, this was not abided by and was rejected by a higher court.

Aggrieved by the above-mentioned decision of the local judge, a new petition was filed by the accused requesting the transfer of the case to a new magistrate. And finally it appears that a new petition has been filed asking for change of judge as well as the place of trial. In addition to these obstacles. the accused have repeatedly requested

stay orders for various reasons, making it almost impossible for Archana to go on with the cse, considering that she is living abroad.

Conclusion

Ten years have lapsed, the case lingers on and still no verdict is insight. At the end of the 1970s many cases were brought against the police for torture; however, all other cases have been dropped. Very few people can keep a court case going for years; the legal expenses involved are astronomical. A very storng personality is needed to go through these ordeals with so little hope of success.

Archana's lawyer has taken on the case on a humanitarian basis. He, himself, has been threatened on many occasions, and threats have also been made against his family. The whole court case seems to be a clash of interests. However, it is difficult to see who the accused party represents. Very expensive lawyers have been helping the accused (and prolonging the court case) all these years, and a question has been raised as to who pays their fees. In whose interest can it be to suppress a court case like this, to keep it from reaching a verdict?

If it had not been for support from internatioinal organisations, local human rights groups, and women's organisations as well as the press and television, this case might also have been dropped years ago. This would not be in the interest of a democratic country like India, where torture is prohibited by law.

In this context, we must also consider the Convention against Torture and Other Cruel, Inhuman or Degrading Treatment and Punishment (4), the United Nations convention prohibiting torture and setting up rules and regulations concerning international aspects of torture. So far, 43 states have signed the document, and of those, as of December 1987, 17 have ratified it. India has not yet signed this document, whose aim is to help progressive authorities bring about justice.

Archana was forced to spend three years of her life in prison, was brutally tortured, and only after intensive rehabilitation has been able to begin to live a reasonable life again. Three years of a lifetime is a long time. Cases of tortures being convicted and punished are virtually nonexistent as are cases of compensation paid out to the victims. More than three weeks of torture cannot be undone; three years of a life cannot be given back. The duty of society must be to compensate at a realistic level as well as to use such occasions to better it control over and insight into various services in our society, including the police. We must remember that the police force reflects that society in general. The time has come to recognise torturers as the criminals they are.

State Torture: Some General, Psychological and Particular Aspects

fernando bendfeldt-zachrisson

State political torture has been practised in Latin American countries and is well-documented. What are the particular aspects of this practice? What are the elements which contribute to a person participating in torture? Who is the real torturer?

WE may describe torture as that extreme and deliberate form of violence inflicted upon a victim who experiences it consciously, and who has no control over its form or duration. It produces pain and mental or psychologial stress and is intended to destroy the victim's will in an attempt to perpetrate a determined order of power relationships. When such practice is structured into the ways a state governs over the people of a nation, we may refer to it as state torture; but when the primary target is the citizens who oppose, or are believed to oppose, the order of relationships established by that state, we may talk of state political torture. In the American continent the use of torture as an identifiable administrative policy has been recognised in several countries [1-4], but the cases of Chile, Uruguay, Argentina, Paraguay, El Salvador, and Guatemala have become exemplary over the past ten years [1, 5-9]. In these countries thousands of citizens who oppose their governments have been (and are being) tortured in semi-clandestine torture centers, where similar methods and techniques of suffering are implemented. The subjects for torture are identified and selected by branches of the military and then kidnapped by "heavily armed men dressed in civilian clothes" who operate with impudent legal immunity. The victims are then taken to camouflaged jails where a minority of those who enter are able to come out alive to tell the story.

What is the purpose of such torture? On first hand it may seem that the answer is information. But if we review the methods and understand that in these countries torture has been made a stable semiclandestine institution of the state, its primary purpose can no longer be considered simply to secure information or a confession. How could we believe information is the aim when pregnant women are burned in the nipples and genitals and then receive electric shocks in the uterus producing either abortion or brain lesions in the fetus [3]? Or when splinters are inserted into the eardrums? And besides the cruelty *per se*, how valid could a confession be under those circumstances or under the effects of stupefacients? No, here the specific purpose served by such brutality seems to be primarily the destruction of the individual in his/her most basic humanity, while the general objective seems to be the attempt to preventing dissidence—a way of exercising and maintaining power by terror.

By definition, torture assumes the involvement of at least two subjects: the torturer, who applying torture strives for maximal submission of the victim under his physical control, and the victim, whose actual circumstance makes an immediate defensive counterviolence impossible. In the following sections, I will examine some aspect of the methods of torture, the torturer and the effects of this practice.

Methods of Torture

When torture is part of the state policy, the methods for destroying the morale and physical integrity of the victims are ample. Breaking down the victim, whether by producing an organic impairment of the mental functions [10] or by the effects of stress [11, 12], is achieved by the use of both rustic and sophisticated methods and techniques. What, when and how to torture is something established by accumulated local and international experience. Not infrequently, it is assisted by modern medicine and research findings, even with direct participation of physicians [13-21]. There are testimonial reports of medical doctors supervising the process of torturing, or monitoring the procedures so that unconsciousness and death are avoided while maximum stress is applied [1].

The scientific approach to torture has been taken seriously by some. In a recent article published in the *Journal of Medical Ethics*, 'On the Permissibility of Torture', G. E. Jones argues in support of torture [22]. Justifying it on utilitarian grounds he states:

> It (torture) cannot involve death, and must utilize the most advanced medical techniques available so as not cause needless psychological or physical harm. Only the minimal amount of pain necessary to obtain information would be inflicted (italics added).

And further, in a clearly marketing way, while discussing the cost-benefit ratio of torture (which he compares with solar energy: it pays in the long run) and under what he calls humane (sic) torture, he goes on saying that:

> The state of technology is such that we can stimulate certain centers of the brain such that we can inflict pain without physical abuse or *physical side effects*. (italics added)

The mode of torture that Jones proposes, which apparently includes electro stimulation or microsurgery to affect brain centers, selectively ignores that torture is terrible as an experience and not only for its visible sequelae. What Jones seems to be concerned with is the public or

observable evidence that torture had taken place, rather than what it represents, or the damaged self and relationships the torture victims are rendered with. Torture is a devastating experience that accompanies the surviving victim the rest of his/her life, affecting, as I will explain later, more than the physical or physiological aspects. Jones' statement that, "Only the minimal amount of pain necessary to obtain information would be inflicted" is naive. Would't a torturer ever accept having inflicted pain in excess of that necessary to his victims?

The pain and the stress caused by different methods of torture need to be multiple, variable and unpredictable. This way the victim's attempts at behaving in consistent ways or developing personal behaviour patterns to better sustain the suffering are frustrated. The methods and techniques of torture are often the same in the six Latin and Central American countries (Table 1), even to the point that many types of torture receive the same name (Table 2)—a case of internatioinal cooperation.

The catastrophic existential event that torture represents for the victim will certainly leave a permanent stigma in the survivor and his/her basic social nucleus. How, and to what extent, the terror, humiliation, loss of dignity and physical suffering will mark the victim is something that cannot be generalised. The structural characteristics of the victim's personality are important: the victim's clarity and strength of morale, sense of purpose and comradeship and even hatred of the system that brings the suffering [21]. But the effects of torture on the victim will also depend upon the dose of experienced violence, that is, the duration and intensity of the stressor.

The extent of the injury should be measured not ony by the bodily deformity or loss, or impairment, but by the emotional significance attached to the experience which often leads to a radical alteration of the person's whole life [23, 24]. Torture results in anxiety, difficulty in thinking, loss of self-esteem, social withdrawal, decrease in productivity and abandonment of goals [1, 14, 23]. For those who can no longer resist and who broke down, additional guilt and despair awaits.

From a psychiatric point of view, torture represents a situation of massive stress which unequivocably provokes anxiety, brought about not only by pain and mortifications, but also by uncertainty. Under torture, the threat of destruction is more than an imminent possibility—it has already started. Yet what the victim lacks is access to knowing how, when or if the destruction is going to be completed. In psychiatric language, the symptomatic post-effects of torture, together with other psychological traumatic events of inordinate nature and outside the usual human experience, fall in what are called post-traumatic stress disorders [25]. Briefly, these disorders constitute a condition that results in the contraction and disorganisation of the ego [26], hence to a symptom complex, acute or chronic characterised by: 1) recurrent and intrusive recolections of the traumatic event and nightmares in which the event is re-experienced as it was or in a representational way; 2) dissociative states that last from minutes to days, in which the individual behaves as if the trauma were recurring, because of an association with an environmental or ideational stimulus that elicits them; 3) constriction of affect, reduced responsiveness to the surroundings, and feelings of estrangement from others; 4) hyperalertness, exaggerated startle response, sleep disturbances, memory impairment, etc. Yet, as has been observed, the symptoms brought forth by deliberate man-made disasters, such as torture, often exceed other stressors in severity and consequences and may even precipitate premature death [27].

Table 1: Methods of Torture[a]

1. Environmental Manipulation:
   - Social deprivation (isolation from family and friends)
   - Isolation (restrictionof company, sex, work, relaxation, food)
   - Sensory deprivation or overload (solitary cells, noises, reflectors, etc.)
   - Sleep deprivation
2. Pharmacological Manipulation:
   - Parenteral barbiturates and stupefacients
   - LSD and related drugs
   - Apomorphine
   - Corrosive chemicals
   - Cyclophosphamide
   - Muscle-paralyzing drugs (e.g., curare)
3. Coercive Methods:
   - Forced seeing or hearing others being tortured (friends, relatives, spouse, children)
   - False accusations
   - Occasional indulgences
4. Somatic Methods:
   - Forced standing: prolonged standing in a required position, usually undressed.
   - Cold water: irrigation or submersion in cold water
   - Beating: with iron rods, rubber truncheons, whips, batons, sticks, etc.
   - Starvation: deprivation of water or food
   - Mutilation: dismembering of various parts of the body
   - Breaking bones
   - Sexual molestation: stripping, touching, attempted rape
   - Rape: homosexual or heterosexual
   - Electricity: electric shocks applied specially to eyes, teeth, head, genitals, rectum; "electric bed"
   - Fire: e.g., welding torches applied to head, eyes, genitals, etc.
5. Psychological Methods[b]
   - Denigration with insults, false accusations, use of brutal and threatening language, threats of execution
   - Sham execution
   - Execution of family members or friends in front of the victim
   - Video or audiotapes of the torture of other victims. including torutre of relatives, spouse and children
   - Witnessing homosexual or heterosexual rape performed on friends, relatives, etc.

a See references 1, 3, 5, 6, 7, 49.
b The separation of psychological from somatic is ony made for clarity sake. Any form of torture encompasses both psychological and somatic effects.

Although not all researchers agree [4], some studies have found that the psychological effects of torture are sufficiently characteristic to constitute a 'torture syndrome' [28, 29]. However, we still know little about what occurs to the human body and mind as the result of torture, notwithstanding the psychic and somatic changes observed. In general, the investigations of long-term psychological effects of torture are rare. However, a recent Danish study [4] sponsored by Amnesty International in which 135 victims of torture were examined medically and psychiatrically gives us an idea. The study showed that at the time of the examination, conducted between six months and a year after torture had taken place, 90 per cent of the victims complained of various symptoms which arose in conjunction with or following torture. Of those, 75 per cent presented psychiatric symptoms which included impaired memory, impaired concentration, mental changes and sleep and sexual disturbances. All the subjects had been healthy prior to their arrest. On the other hand, Allodi and Cowgil [28] investigated 41 cases of torture among the thousands of refugees from especially one Latin American country, who had migrated to Canada. The victims studied were 32 males and nine females, whose ages ranged from less than ten to 46 years of age (mean age 26.9). Twenty-five per cent of them had some university training; and except two females, they had experienced a total of 112 incarcerations ranging from weeks to a year (one victim had been imprisoned 11 times in five years). All were subjected to physical and psychological abuse. Allodi and Cowgill concluded that all suffered from a homogenous psychological disorder marked by severe anxiety, insomnia with nightmares about persecution, violence or their own torture experience, somatic symptoms, phobias, suspiciousness and fearfulness. In the case analysis they found that there seemed to exist a positive relationship between the individual ideological preparation, commitment and group support and psychological recovery from torture.

The sequelae at times could lead also to lesions in organs of functions not directly subjected to torture. For instance, Lunde, Rasmussow and collaborators (30) studied the sexual function of 17 men exposed to torture. They found that independently of cranial or genital trauma or severity of torture, 19 per cent of the studied victims presented sexual dysfunctions manifested as decrease in libido and/or erectile dysfunctions, in absence of abnormal pituitary or gondal hormones. In another study, Jensen Genefke and collaborators reported cortical or central cerebral atrophy, as determined by computerised axial tomography, in five non-alcoholic, previously healthy men ages 24 to 39 [31]. These men had been exposed to severe and prolonged tortures (mean of four years), and all had symptoms consisting of inability to concentrate, headaches, anxiety, depression, asthenia, sleep disturbances, cerebral asthenopia and sexual dysfunctions for several yars. A suggested possible mechanism, assuming that the atrophic changes cannot be attributed to head trauma, has been the possibility of high levels of cortisol secondary to the chronic severe stress of torture[32].

> We did not dare to kill them all (the political prisoners) when we could have done so and one day we shall have to release them. We must take advantage of the available time in order to make them go mad.
>
> Major Arguimides Maciel
> Director of Libertad Prison
> Uruguay

When confronting human behaviour, especially if it is deemed highly negative in quality, psychiatrists and field-related professionals tend to seek the roots of such behaviours primarily in the individual, or, at best, in his/her immediate surroundings. In such a narrow view, the torturer's behaviour could be easily conceptualised as one of a sadistic sociopath, brought about by defective parental discipline resentment over emotional deprivation, or more reductionistic, by congenital deficits or neurochemical imbalances in the brain. The problem with this intrasystemic orientation is that it selectively assigns causality intensively to one or a few individual elements, while disregarding or simply enumerating socio-economic conditions as aggregate factors in a multidetermined causality. The socio-economic system and the culture that derives from it is a basic element that shapes (and is shaped by) history, that dictates priorities and modifies environments.

Table 2: Specific Methods

'Submarine or 'Underwater treatment'	The victim is forced to submerge the head in a sink or bucket full of excrement, urine and water.
'The Hood:'	The victim's head is forced into a plastic bag, usually containing insecticide, until suffocation.
'Telephone:'	Beating from behind simultaneously on both ears.
'Parrot Perch' or 'Pau de Arrara'	The victim's wrists and ankles are tied together and the whole body is suspended from an iron bar under the knees, leaving the naked body doubled over and defenseless. In this position electro-shocks are applied and filthy water forced into the mouth.
'Dogs Pit:'	The victim is kept a few feet above the ground as (s)he is hanged from the hands which are kept tied together on the back.
'Hook' or 'Hanging:'	The victim is hanged from a rope which is hooked to a strap around the waist, while the hands are tied to the back.
'Mitrione's vest:'[a]	The garment is gradually inflated until it crushes the victim's ribs and makes breathing impossible.
'Picada:'	A straight pin inserted most commonly under the victim's fingernails.

a Named after Dan Mitrione, a North American AID official, allegedly an advisor to the Urguayan police in counter insurgency techniques, including methods of torture [3, 9].

By focusing on the individual or his/her immediate family as the source of aggression, this theory avoids a critical examination of the problem. It ignores the history of societies which value highly certain types of aggressive behaviours, which glorifies the aggressive war hero, and which pretend that amassing destructive power is a deterrence of war and a preserver of peace. In other words, for the study of the individual that concerns us here we must look beyond the individual and his/her family, into the conditions that typically prevail in society which favours—and benefits—from such practices. The political torturer works in the name of the society, the army, the interest of the nation, etc. He is not the isolated maleficarum that our conscience would like us to believe; he is a member of an organised group that operates semi-autonomously, but does so under the direction of branches of the government—an element of a network devised to preserve power and facilitate domination. Does this mean that anyone could become a torturer? The answer is not black or white. Perhaps a now classical experiment better illustrates the dilemma. Some years ago S. Milgram conducted an experiment, 'Behavioral Study of Obedien cy' in a laboratory at Yale University [33]. The experiment consisted of 40 volunteers who were led to believe that they were to take part in an experimental design on memory and learning. Each volunteer was instructed to administer electric shocks to a learner-victim whenever (s)he gave an incorrect answer to a question. Although the victims never actually received an electric discharge, they had been instructed to pretend as if the shock had been experienced. The experiment was designed so that when the punitive shock had reached certain voltage, the teacher-volunteer had the option of stopping the procedure, but was verbally encouraged, and even firmly ordered to proceed administering shocks at higher voltage if the learner-victim failed to complete the task. In the experiment none of the 40 subjects stopped prior to shock level 300, at which the victim began kicking the wall and no longer provided answers to the multiple choice questions. At the end of the experiment 26 of the 40 subjects completed the series by administering 520 volts.

This experiment tells us about human potentialities, and how given the manipulation of certain variables, one can end up doing something contrary to one's expectations. Certainly, there are many aspects of the experiment that one can question, eg., who were the real victims here. But besides that, let us not forget that this experiment was conducted in one of the most prestigious universities in the United States, in the name of science, and in a contemporary industrial society where science is highly regarded. Therefore, the setting was one in which the average person would have difficulty believing that such an experiment could be wrong [34]. Many of the participants continued to shock the victims under much stress and pain, fighting the contradictoms and trying to justify the scientists' recommendations.

The point of this experiment is that ascribing to the individual torturer a particular psychopathology reveals nothing, unless there is interest in maintaining that if there were no sadistic-sociopaths, or that if they all received some sort of psychotherapy, this type of practice would stop.

How does the torturer become a professional in torturing? First, the external and material circumstances of his background must be such that will accommodate his nefarious occupation with relative ease. Second, he must be educated to be efficient and perform his work with determination. This eduction, given in schools of torture [1,35], sometimes with "instructors" from other countries [3, 35], aims not only at providing the torturer with the techniques for torment, but also at preparing him psychologically and ideologically for his labour. How is this mental preparation achieved? First, it is done by emphasising the non-humanness of target groups. The victim needs to be perceived as a thing, as something contrary to what the state, and the social class it serves, regards as the communal good—by educating this way the propitious condet is motivated and targeted. Secondly, training is done by conditioning the prospective torturers that they are to act for the good of the nation, the good of the country. Therefore, even the most brutal actions do not constitute a violation of the high moral principles under which they allegedly operate. Third, by education that emphasises loyalty to an organisation that will protect the individuals involved and maintain secrecy. This services to exculpate residues of personal responsibility while subordinating individual will to that of the organisation. Fourth, instructors simulate an aura of mysticism aimed at encouraging a long-term commitment and group cohesiveness. Torturers are frequently called by pseudonyms that stress certain personal characteristics, and some are even referred to as doctors [1, 36].

Despite these training and accommodating personality traits, it is likely that the torturer experiences some mental stress by tormenting his victims, and realizes that he is also the object of exploitation. He is usually a low-ranking employee likely belonging to a social class exploited by those whose interests he serves, and the mean for ends that are not truly his. This situation not only places him in severe contradiction that resonate in his practice, but also demands attempts at resolution on the personal level.

According to Festinger [37, 38], if an individual holds two ideas of mental sets that are not psychologically consistent with each other, he will experience discomfort produced by such inconsistency (or dissonance). In order to resolve the conflict the individual will either change both ideas or add a third one that will bring about less incon-

sistency. In other words, he will have to come up with something that will convince him that one of the ideas or sets is worth pursuing, especially if the ideas have already been transformed into acts. What is characteristic here is that the arousal of dissonance always contains personal involvement, and, in order to reduce the dissonance created, self-justification is the rule.

If we extrapolate this to the situation facing the torturer, then we can see that he finds himself in a dilemma: he needs to rationalise, to deny, to protect himself from the perception of his own doing. He needs to obtain some (subjective) gains, or else, due to the nature of his practice, he runs the serious risk of being flooded with unbearable stress that would break into his psyche and probably make him collapse (testimonies of victims of torture and agencies for human rights indicate that frequently the torturers torment their victims in a state of alcohol intoxication or under the effects of drugs [39]). The literature reviewed does not contain interviews or direct 'studies' on the psychology of the torturer, but by the nature of his practice and the accounts given by some torture victims one can infer some of the major psychological response mechanisms assisting the torturer. First, the torturer, not blind to the perceptions of his own doing, needs to distort reality, to exculpate himself from what and how he does, and to come up with maneuvers that would obscure the relationship between his actions and the effect they cause. Here the basic mechanism is projection: the victim is held responsible for his/her own suffering, a "you're getting what you looked for." But that transfer of blame is probably not sufficient, for the torturer knows he himself is the victimiser. Something more is needed: the torturer needs to dissociate himself from the victim, create distance, and he does it by ascribing a derogatory status to the victim (something he has been taught to do) which is, in a deeper level, a projected hatred of his practice and of his ultimate sponsors, and that *that* he will destroy in the victim. The contention here is not that the torturer is *the* victim, but rather that the problem is, we may say, dialectical. The torturer is the victimiser, but he has within himself the victim which he denies. That is, he conjures out his condition of (also) victim, by projecting it onto the tortured, and proceeds to destroy it. Thus, by torturing his victim, the torturer obtians three victories: one that comes from the triumph of having projectively annihilated his own feelings of victimisation by torturing others. Another victory is from avenging in the victim, his own displaced hatred toward those for whom he works and who are the real beneficiaries of his necrofiliac activity. But also, at another level, by torturing the victim, the torturer obtains a triumph over his own fear of retaliation and death, by being in absolute control over the lives of others.

Conclusions

To know and not to act is as if not knowing at all.
Old Japanese Proverb

Torture, as a structured apparatus used by nations to structure and maintain a given order of power relations, constitutes part of the daily experience suffered by thousands throughout the world. The case of several Latin American countries, whose governments not only declare themselves democratic, but which are also referred to as democracies by other governments, is a crude and typical example.

Here, I have described some aspects of that particular kind of torture, its known short-term and long-term effects, and its purposes, and elaborated on some psychodynamic elements under which the man who carries on with torturing probably operates. Of course, these elaborations do not pretend to be exhaustive, nor are they intended to be an apology for the men who actually do the torturing. Rather, the point is that these men should be understood in the historical and social context in which they operate, without forgetting who pays, who supports and who benefits from their practice. Fortunately, there exists throughout the world agencies and organisations concerned and vigilant of human rights which have bravely denounced torture, but unfortunately, those who are in the position of strength to exert necessary effective pressure over nations which indulge in such practice give lip-service criticism, or plainly ignore it.

Finally, I want to briefly mention another type of state torture that should concern us, but which due to its nature and implications will require a separate study. I am referring to the systematic, well-orchestrated and 'dosed' psychological and physical violence that a country, by virtue of its economic and military might, exerts over smaller nations and their people. Such smaller nations, due to their own historical and concrete existing conditions, lack the effective means to prevent such violence, or to respond with a likewise effective (defensive) counterforce.

[I want to express my appreciation to Dr. Kathy Blee for reviewing this manuscript and helping to make it more legible. My appreciation also to Virginia L Gift who patiently typed and retyped the manuscript.]

REPRODUCTIVE AND GENETIC ENGINEERING

[Journal of International Feminist Analysis] [(published three times in a year)] RGE is designed to facilitate the development of feminist multi-disciplinary and international analysis on the new reproductive technologies and genetic engineering and their impact on women worldwide. The policy of the journal is to recognise the use and abuse of women as central to the development of reproductive technologies and genetic engineering and to highlight the relevance of the application of these technologies to the past, present and emerging social and political conditions of women.

RGE is edited by International Editorial Collective and Editorial Advisory Board.

Participation of Doctors in Torture

Report from Pakistan

mahboob mehdi

Under the dictatorship of the late Zia ul Haq, the state legalised and actively used torture as a form of punishment in Pakistan. Invoking Islam and its so-called laws, 'the medieval practices of flogging, amputation, stoning and so on were put to widespread use. Although the government has changed, these laws have not been repealed, nor have those who practised them, including the medical profession who colluded in these acts been punished. This paper was circulated at the at the AI's conference on 'Medicine at Risk'.

TORTURE has never been taken seriously in the official medical circles of Pakistan. The teaching of health professionals in various institutions of Pakistan does not bring into consideration the question of torture and how health professionals should react to it. The code of medical ethics of the Pakistan Medical and Dental Council does not mention any thing about torture. Doctors who take part in torture do not face any disciplinary action by the Pakistan Medical and Dental Council. In Pakistan the participation of doctors in the process of torture is usually legal and has been made part of the duties of the doctors.

The following types of the medical participation in the process of torture is seen in Pakistan.

(1) Under the execution of the punishment of the whipping ordinance of 1979—before the execution of the punishment commences, the convict shall be medically examined by the authorised medical officer so as to ensure that the execution of punishment will not cause the death of the convict. If the convict is ill the execution of the punishment shall be postponed until the convict is certified by the authorised medical officer to be physically fit to undergo the punishment. The punishment shall be executed in the presence of the authorised medical officer at such public places as the Provincial Government may appoint for the purpose. If after the punishment has commenced the authorised medical officer is of the opinion that there is apprehension of the death of the convict, the execution of the punishment shall be postponed until the authorised medical officer certifies him physically fit to undergo the remainder of the punishment.

(2) In many interrogation centres, the person to be interrogated is examined by the doctor and declared fit for interrogation.

(3) The conduct of the prison medical officer in most of the cases is very unethical and falls very short of the United Nation's declarations and codes of conduct. Instead of providing the standard and best available treatment to the prisoners, the prison medical officers usually behave as part of the prison administration and take part in torture.

(4) Cover-up activities by some doctors such as providing false death certificates or false clinical records of the victims of torture is very common.

(5) If the court orders amputation of a hand or a foot as punishment then according to the law it will be carried out only by an authorised medical officer personally.

(6) I have interviewed men and women who were tortured in different torture chambers and prisons of Pakistan. These victims have given evidences about the participation of doctors in the process of torture. One of the victims interviewed is a doctors and he faced his own class fellow-doctor in the torture chamber.

Usally the doctors:

(a) Advice the tortures about the actual condition of the victim's health.

(b) Revive the victims sufficiently to undergo further torture.

For the first time in the history of Pakistan, we in the Voice Against Torture (VAT) have systematically raised the question of medical ethics in relation to torture. In a three-day seminar held in Islamabad one full session was devoted to medical ethics in relation to torture, corporal punishment and other forms of cruel, inhuman or degrading punishments. We appealed to the Pakistan Medical and Dental Council to incorporate in its ethical code a clause against torture in line with the Declaration of Tokyo. In this session we declared that nobody in the world is medically fit for flogging. So doctors must not declare anyone fit for flogging. After the intervention of VAT in the medical scene of Pakistan more and more doctors have responded to the problem of torture. Thus recently at the 7th International Psychiatric Conference held in Karachi, different aspects of torture were discussed in a seminar attended by a good number of doctors. VAT fully coorperates in all such activities with its experience and documentary resources.

Torture was always endemic in Pakistan but during the last decade it reached epidemic proportions. Authorities often try to legitimise many crimes of torture by taking cover under religion. Due to this reason we are using the Declaration of Kuwait along with the Declaration of Tokyo. The Declaration of Kuwait is a good document relevant to the Muslim societies. It says:

> The medical profession shall not permit its technical, scientific or other resources to be utilised in any sort of harm or destruction or infliction upon man of physical, psychological, moral or other damage... regardless of all political or military considerations.

Voice Against Torture has been organised to achieve the following aims in Pakistan:

(1) To disseminate information among the people about the methods and purposes of all forms of torture prevalent here.

(2) To mobilise public opinion for the eradication of all forms of torture.

(3) To make the doctors realise that torture is a serious challenge to the medical profession.

(4) To make efforts that knowledge of torture and knowledge of the methods of treatment of people who have been tortured is incorporated in the teaching courses of doctors, physiotherapists, nurses, psychologists and social workers.

(5) To mobilise the opinion of the doctors in favour of the 1975 World Medical Association's Declaration of Tokyo.

(6) To make representation to Pakistan Medical and Dental Council to put the clauses against torture in it's code of medical ethics.

(7) To ensure that doctors do not participate in any procedure of torture. i e,

(a) They do not take part in cover-up activities such as providing false death certificates or false clinical records of victims of torture.

(b) They do not monitor torture by remaining present during any act of torture or by declaring any person fit for torture or by advising how far the tortures may proceed or by reviving victims sufficiently to undergo another bout of torture.

(c) They should not use their professional skill to extract information, control the prisoner or simply on punishment.

(d) They should strive to provide the best quality treatment to prisoners and people in detention; and should not have a biased attitude with them.

(8) To give all the support to the doctors who refuse to participate in the acts of torture, so that they and their families are not victimised by the different agencies of the state.

(9) To collect evidences against the doctors who have choosen to become instruments in the procedure of torture. To present these cases to the Pakistan Medical and Dental Council for necessary action; and to take these cases to the court so that the doctors may be tried for their criminal acts; and to expose them widely in the public and media.

(10) To mobilise opinion among the community of scientists in such a way that they should refuse to make instruments which could be used in the process of inflicting torture.

(11) To do research on all forms of torture, their effects and methods of treatment including rehabilitation.

(12) To provide free medical facilities for the treatment of victims of torture.

(13) To provide necessary specialised professional information to doctors who are treating victims of torture.

(14) To establish a specialised centre where victims of torture of any type could be referred from anywhere for treatment and rehabilitation.

(15) To keep cordial relationship with other anti-groups in the world. To exchange experiences with them and to participate in joint activities and seminars etc., with them.

(16) To cooperate with other human rights organisations nationally and internationally. To join hands with them for the struggle to eradicate torture throughout the world.

One important point to consider is that it is torture which has produced the struggle against torture. Geographically torture is not limited to few places. Irrespective of faith and ideology torturers are united internationally. They cooperate with one another. They exchange experience and technology. They do not like the struggle against torture. Those struggling against torture are in danger of becoming their victims themselves. It is, therefore, very important that those struggling against torture must also unite internationally irrespective of faith and learn from one another. They should exchange experiences and technology of the struggle against torture. They should plan measures for the protection of persons involved in anti-torture work in high risk areas.

Those involved in the struggle against torture and engaged in the task of treatment and rehabilitation of torture victims in high risk areas like Pakistan and many other third world countries need protection to ensure smooth, efficient and safe functioning. The following steps may serve this purpose:

(1) Recognition by the U.N. and relevant affiliated organisations.

(2) Support by Amnesty International.

(3) Support by different anti-torture organisations of the world.

(4) Support by different human rights organisations of the world.

(5) Participation in international seminars etc.

(6) Wide coverage in the international media.

Doctor and Prisoner

Indian Prison Manual

colin gonsalves

THE Prison Manual contains several provisions relating to the health and well being of the prisoner. The duties of the Medical Officer are set out in Chapter IV. He has to keep a check on the medicine and the water supply. He shall oversee general sanitation. He shall examine and treat prisoners.

Under the provisions of Chapter XXXVI, when a prisoner dies, a report is to be made and submitted and the doctor plays an important role in this. If the prisoner is seriously ill and dies the relatives must be informed. If the death of the prisoner is "under circumstances raising a reasonable suspicion that some other person had committed an offence" this has to be reported to court in order that an inquest be held. Notices of death must also be sent to the municipal officer of health.

Immediately on the death of the prisoner the medical officer must be informed. The body must be left in the position found until the doctor examines the body. The medical officer is to prepare a report relating to the background of the prisoner and the circumstances of his death. This report along with the history of each prisoner is preserved for two years. Chapter XLV is titled 'Lunatics'. Normally most sick persons are to be sent to mental asylums. The provision most often relied on however, is the one which permits the government to keep the prisoner in a jail if no mental hospital is available for treatment of the prisoner. The exception to the rule has become the rule itself. Records are required to be maintained of the condition of the patient and the treatment given for a period of two years.

Criminal Procedure Code

Section 53 of the Code is as follows:

> 'When a person is arrested on a charge of committing an offence... that there are reasonable grounds for believing that an examination of his person will afford evidence as to the commission of an offence, it shall be lawful for a registered medical practitioner, acting at the request of the police....and *for any other person acting in good faith in his aid* (emphasis added)..., to make such an examination of the person...

Often this section is misused by the police. After torture the accused is sent to a doctor specially known to the police and co-operating with them for a medical report that the person was fit or for a report that injuries were found but they were inflicted by fellow prisoners.

Section 54 of the Code provides for medical examination of the arrested person at the request of the accused.

> When a person who is arrested alleges... at the time when he is produced before a magistrate or at any time during the period of his detention in custody, that the examination of his body will afford evidence... which will establish the commission by any person of an offence against his body, the magistrate shall, if requested by the arrest person... direct the examination of the body... by a registered medical practitioner...

Section 174 relates to the mode of inquiry to be conducted by the police in the case of deaths.

> When the officer-in-charge of the police station... receives information that a person has committed suicide, or has been killed by another.... or by accident, or has died under circumstances raising a reasonable suspicion that some other persons has committed an offence... he shall make an investigation, and draw up a report of the apparent cause of death, describing such wounds, fractures, bruises and other marks of injury as may be found on the body....

Note that the medical officer is not involved at any stage in this investigation. A complete medical examination is expected to be done by a lay person.

In the case of the death of a woman however, the section provides for an examination by the "nearest civil surgeon *or other qualified medical men appointed in this behalf by the state government* (emphasis)".

It would be interesting to study the background and performance of the doctors appointed by the government. In many cases it appears that these persons appointed must 'qualify' in that, they must be willing write reports and conduct examinations according to the bidding of the police. The need for an independent body of doctors free from the intrusive forays of government is most necessary.

Some Cases

Veena Sethi's Case (AIR, 1983, SC. 339) drew the attention of the Supreme Court to the atrocious conditions of the prisoners in the Hazaribaug Central Jail rendering them insane. The prisoners were detained in jail for very long periods of time though they were declared insane because "there were no adequate institutions for treatment of the mentally sick". The judge's were told that there was only one institution in the state of Bihar, for the treatment of the mentally sick and that was the Mansik Arogyashala but that was overcrowded. The judges said "we have had occasion to see lunatic asylums in one or two states and we find that the conditions in these is wholly revolting and one wonders whether they are placed for making insane persons sane or sane persons insane".

The court then took up the case of Gomia-Ho. He was convicted in 1945 and sentenced to three years in prison. In 1948 he was found to be of unsound mind and directed to be kept in the Hazaribaug Central Jail since there was no place in the mental hospital. Half yearly reports regarding his mental conditions were required to be submitted

Implication of Physicians in Acts of Torture in Uruguay

gregorio martirena

In 1984, prompted by public protest against the widespread use of torture against political prisoners, a National Committee on Medical Ethics comprising doctors, medical students and lawyers was set up. Its findings have led to the drawing up of a Code of Procedures for trying the numerous complaints against the doctors participating in torture. (Reprinted from the Danish Medical Bulletin, *August 1987)*

FOR us physicians who have had the sad privilege of living for over a decade under totalitarian regimes that practise terror and torture and which, in turn, are supported by multinational expansionist economic interests, there is a pressing need to develop and refine international medical initiatives against torture. For those who govern by applying the National Security Doctrine, torture is a basic was fundamental element. In the words of my Chilean colleague, Dr. Serio Pesutic, there is no better way to defining torture than as *a dehumanised use of power.* Torture is implemented by those who are dominant, especially against those who threaten to undermine submission to their rule.

Torture has a Dante-esque etiology. It is the only man-made disease whose intention is here and now. In it, the first sick factor is neither the victim nor the torture, but rather the society which provides the opportunity and incentive to use torture. In all its degrees and expressions torture is nowadays deeply selective. Those who suffer it are those who are able to organise large crowds of people and who follow their own conscience. Torture tends to damage individuals without causing them to die, rather than obtaining information from them. This has led to the need for physicians to participate in implementing and sophisticating it. Among other things, means are sought to torture without leaving marks in order to make any denouncement lose legal validity, since such complaints are exclusively based on the testimony of the victims which is met with the cynical denials of those responsible in the security services.

Today, we are able to single out these points as the cornerstone of torture in the Third World. This, then, is the time when the figure of the military doctor assumes a central role as protagonist in his functions, his practice, and his aims.

Until the beginning of the early 1970s, the great majority of medical doctors who served the health units of the Uruguayan Armed Forces did so as civilians practising their profession. The Armed Forces Function Act (No. 14,157) along with Article 50 of Decree No. 783/73 ordained that the practice of their rights and the fulfilment of their professional duties be subordinated to military regulation. Likewise, their professional tasks were subordinated to the military authorities in direct opposition to the universal values of medical ethics.

The adoption of the National Security Doctrine meant an ideological purge of the armed forces, since anyone considered a danger to that ideology was dismissed from his post. Undoubtedly, this fact along with the abovementioned decrees make it absolutely valid to say that the military doctors were the medical part of the repressive apparatus which committed innimaginable gross violations of human rights. To many people, such affirmation may seem too simplistic; but here we are not talking about the ordinary man in the street or about those who had no other job opportunity than to enter a military garrison. We are talking rather about physicians trained culturally and scientifically at a free university. This is why we cannot understand that they have collaborated with those who directly oppressed our entire people.

The University of the Republic and the Uruguayan medical profession have been the primary pillars of our social gains for more than 40 years. For these institutions, every medical doctor owes respect and, above all, the doctor's respect is owed to a professional condition that identifies him or her with the health of others. Impositions from the established hierarchies can only alienate them from carrying out their professional duty, resulting in a serious disregard of medical ethics.

Consequently, a military doctor is not released from his ethical responsibilities if he enters service in the armed forces, since this only constitutes a minor addition to his fundamental condition of being human and being a physician—conditions from which he can never be returned. The implementation of an alienating training system with the imposition of a discipline aimed at estranging him from his humanity and his moral conscience as a doctor is impermissible. It is also incompatible with real medical training and with responsibility for the training of other doctors, because for these situations the greatest measure of freedom of conscience is required.

Although this is an affront to medical life in Uruguay, it is an historical fact that certain military doctors participated actively or passively in torture or violated ethical norms they ought to have abided by when carrying out orders from their superiors. In addition, we find a collective responsibility on the part of military doctors for neglecting to issue denouncements when such acts occurred—even today, a year and a half after democracy has been restored. This happens despite the fact that they belong to an institution which unquestionably has implemented measures that violated human rights on such

a wide scale and with so ample evidence that no one could ignore it.

In July 1984, the 7th National Medical Convention took place. On this occasion, public denouncements were reiterated of the systematic torture used against political prisoners as well as the violation of basic human rights on the part of the dictatorial government in Uruguay. Faced with these facts, a National Committee on Medical Ethics was set up. Its task was to study the denouncements and make decisions on them. Moreover, it was to prepare the elaborate a preliminary bill of compulsory medical association membership with its corresponding ethical code. These are long-standing aspirations of the Uruguayan medical profession that even today have not yet been achieved.

As a precedent, there is the decision made by the Uruguayan medical profession on October 27, 1984 to expel Dr. Eduardo Saiz Pedrini. Before that, an extraordinary tribunal set up by the Medical Federation of the Provinces found him guilty of violating the principles of medical ethics of the United Nations by giving perjured evidence in the certification of death and by covering up the torture suffered by Dr. Vladimir Roslik, who died on April 16, 1984, at Fray Bentos Military Garrison.

On March 4, 1985, the National Committee on Medical Ethics commenced functioning. It was made up of physicians representing the Uruguayan Medical Union and the Medical Federation of the Provinces along with the Association of Medical Students; in addition, it included members representing the Uruguayan Bar Association and its Human Rights Committee.

From the outset, and as the denouncements from released political prisoners began to pile up, those who had the honor to be designated members were faced with an incredible range of horrors. The constant factor in them all was that physicians played an active or passive part. There were the doctors who took down data on the prisoner's entrance record. This enabled those who were directly in charge of the torture procedures to know the person's physical or mental weakness or disability, enabling them to act with a maximum of ferocity on those points. There were the doctors who were unconcerned about giving direct care to sick prisoners, who delayed consultations, refused medication and specified diets, etc; the doctor who stepped in when the torture victim's life was at stake, thus succeeding in returning him to consciousness, only to send him back into the torture machine; the doctor who falsified the death cause of prisoners, performing incomplete autopsies or issuing death certificates many times without directly examining the bodies concerned; and the doctors who directly participated in torturing those interrogated or conducted a constant mental harassment of the prisoners, seeking ways to break down their personalities.

In this notes on *Reflexiones Para un Judicio Etico-Medico* (Reflections for an Ethical/Medical Judgment), Dr. Rodolfo Schurmann P., expert in criminal law and member of the National Committee on Medical Ethics, writes: "Many of these practices can be comprised within criminal offenses such as *injuries, abuse against detainees, private violence, covering up,* and *failure to offer medical care.* This does not mean that they are not reproachable from an ethical/professional viewpoint; on the contrary. Taking into account the seriousness of the malpractice, this goes beyond the strictly ethical field and falls into that of criminal law. Thus, two negative judgments can be passed which may coincide in the sentences, but where each is independent. It is true that, as a rule, all criminal acts involve an ethical depreciation, but not all ethical deprecation involves crime. The principle of legality underlying criminal law eliminates in this regard the elasticity or fluctuation of ethical norms *(nullum crimen sine lege).*"

In our country, there has been neither a regular organ specifically for 'trying' unethical conduct nor an applicable code. Thus, the new committee faced the need to study the existing principles for it to act upon:

A *Internationally Approved Principles*

Global:

—The Universal Declartion of Human Rights, 1948.
—The Declaration of Geneva, 1949.
—International Agreement on Civil and Political Rights, 1966.
—Declaration on the Protection of All Persons from Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment, 1975.

Regional:

—The Pan-American Convention on Human Rights, 1969.

B *National Regulations*

—Act No. 1088 of 1870 (concerning the Army: abolition of flogging and other punishments involving torture).
—Present constitutional precepts in force: Articles 26-72 and 332 of the Magna Charta of 1967.
—Act No. 15737 on Nonreciprocal Amnesty, issued on March 22, 1985.

C *Special Regulations and Codes of Ethics*

—The Declaration on Tokyo, adopted by the 29th World Medical Assembly, 1975.
—Principles of Medical Ethics, United Nations, 1982.

According to Dr. Schurmann, the fundamental guidelines—one could almost say the cornerstone—in the worldwide system of ethical responsibility in this field are those adopted by the United Nations General Assembly on December 18, 1982.

Principle 1

Health personnel, particularly physicians, charged with the medical care of prisoners and detainees have a duty

to provide them with protection of their physical and mental health and treatment of disease of the same quality and standard as is afforded to those who are not imprisoned or detained.

Principle 2

It is gross contravention of medical ethics, as well as an offense under applicable international instruments, for health personnel, particularly physicians, to engage, actively or passively, in acts which constitute pariticipation in, complicity in, incitement to or attempts to commit torture or other cruel, inhuman or degrading treatment or punishment.

This is a clear affirmation of the concepts dealt with stating that *without exception of any kind* the supreme duty of all medical doctors is to prevent and cure disease for the patients who are entrusted to their care and to help them avoid suffering. The specific duty of military or police doctors is to offer the imprisoned persons the same health protection and the same treatment as they would give to nondetainess. Correlatively speaking, their highest duty is not to inflict on the people who are deprived of their liberty any sort of cruel, inhuman, or degrading treatment. By virtue of the profession they exercise, physicians hold unimpeachable duties vis-a-vis mankind which extend beyond considerations of interest in the personal, economic, admnistrative, political, or 'national security' spheres.

Furthermore, it became necessary for the committee to draw up a Code of Procedures for dealing with and trying the numerous denouncements it received. In this manner, the accused physicians will enjoy the widest possible guarantees for their defense and discretion about the alleged offeness.

In each case, at the committee's plenary session, an inquiry team is set up consisting of a physician and professional aspects while the lawyer ensures that the correct procedure is abided by. After studying the case in depth, including a justification from the alleged offender, who has a right to legal advice and may call witnesses, the team writes its final report. Subsequently, this is submitted to the full committee for approval, amendment or rejection. If it is approved, the accused doctor is informed. He is then offered a chance to present an apology; if this is accepted by the full committee, a new trial is stipulated. Should the concerned doctor not wish to respond, the ruling is put on record.

After the ruling is official, the next step is up to the medical doctor's professional associations (*Sindicato Medico del Uruguay* and *Federacion Medica del Interior*). They decide on professional disciplinary sanctions according to the details of each case and bring relevant legal action when necessary.

The National Committee on Medical Ethics has now been functioning for a year and a half, and we can show the world only three verdicts on the participation of physicians in torture, despite the fact that we are looking into more than a hundred specific denouncements.

Today, a year and a half after the democratic government was installed—and despite the official mission of the Uruguayan government, which led the United Nations to lift its sanctions against the country for violations of human rights during the years of dictatorial government—we can show the world only a small total of publicly established violations of human rights despite the fact that the whole nation is convinced that such violations took place; a completely intact army with its intelligence and security systems still in force and constantly pressuring the government's political decisions; a state which has not yet determined whether a civilian or a military court is to be in charge of prosecuting those responsible for the misdeeds of the past; and only one bill of Regulations for the protection of Human Rights, namely No. 433 of December 1985, proposed by Senators *Alberto Zumaran and Hugo Batalla* on behalf of the political opposition parties and which has not yet been dealt with in any depth.

Facing the reality of *obstacles* imposed by the government, we as physicians feel proud of the few, but unbending penalties and denouncements made against those who violated the universal ethical principles while carrying out their functions as military doctors. *Now, once again we turn to the worldwide medical community for solidarity and to propose some joint course of action*:

—A set of rules adopted by medical organisations everywhere which shall be binding for physicians when exercising their profession, for their relationship with the society they live in and with the government they are attached to.

In her study on 'Deontology and Repression' Dr. Susana Eirin, a lawyer and member of the National Committee on Medical Ethics, says that in times of moral decay, when a society enters a crisis, all its members are affected by such "memoral shakeup." Before learning to become a physician, one has to learn to become a human being. It may not be possible to lay down exact guidelines for the behaviour of individuals in an environment that is becoming difficult; but it certainly is important for those who start practising a profession to be given norms of conduct in the face of the social crises which our societies in transition have to endure.

—It is necessary to define and implement universal teaching norms on human ethical and professional standards. In particular, the concept of due obedience, or obedience to superiors, should be defined as restrictively as necessary in order to avoid its use as a justification for any conduct violating human rights.

Mission to Chile

Report of World Medical Association

andre wynen

Since 1984 the Chilean Medical Association has been actively campaigning against the use of torture and against the physicians who participate in it. In July 1986 during a general protest strike two office holders of the association were arrested and taken to prison. The association invited the secretary general of the World Medical Association to help free them. This is a report of that visit.

DR. J. L. ONZALEZ REUES and Dr. F. Rivas Larrain, president and secretary general of the Chilean Medical Association, were arrested on July 10, 1986 and taken to Capucinos, an annex of the public prison in Santiago. In the last three years, the Chilean Medical Association has been campaigning vigorously against the use of torture and against physicians who participate in it. I had been to Santiago, Chile, in February 1984 to hold a press conference in which I expressed the WMA's full support of the actions taken by the Chilean physicians.

Last year, the Chilean Medical Association joined other professional groups (lawyers, engineers, arthitects, etc.) to create a national civic assembly. Dr. Gonzalez was elected its president. The purpose is to unite all groups opposed to the regime. The Chilean Medical Association's main cause is to defend the rights of the patient and medical ethics, which is directly linked with the defense of human rights.

The National Civic Assembly called a two-day general protest strike (July 2-3), during which violent confrontations between civilians and military patrols led to three deaths and several injuries. Two young demonstrators were seriously burned, their bodie were found near the airport.

The version given by the opposition—based on testimony by witnesses, including that published by the Catholic Church—affirmed that an army patrol had poured gasoline over the victims. On the other hand, the government version stated reports by their witness that the accident had been caused by the victims themselves while handling Molotov cocktails. One of them died from the severe burns received.

Fourteen leaders of the National Civic Assembly—including Dr. Gonzalez and Dr. Rivas—were detained on charges of inciting to riot and violence during the demonstrations.

Alerted by the Chilean Medical Association, the WMA secretary general issued a press release to international press agencies informing them about the situation and sent letters and telegrams to the Chilean government and the judiciary appealing on behalf of the two collegues detained. These measures were taken in concert with Amnesty International and the American Association for the Advancement of Science (AAS), among others. On July 24, the Chilean Medical Association telephoned and asked me to travel to Chile to help them in the effort to free their president and secretary general.

Contacts were made with the Belgian Minister of Foreign affairs and the Chilean ambassador in Brussels to discuss the feasility of an urgent mission to the Chilean government and the judiciary. Several meetings were arranged in Santiago with the help of the Belgian ambassador in that capital. In August, I arrived in Santiago to meet with the Belgian ambassador and with representatives of the Chilean Medical Association, thanks to Dr. Jorge Jimenez de la Jara who assisted and interpreted during my stay in Santiago.

On Sunday, August 3, the first visit to Drs. Gonzalez and Rivas took place and preparations were made for the forth-coming meetings with government authorities and the judiciary. My last day in Chile, August 6, a second visit with the imprisoned colleagues was allowed and prior to my departure for the airport, a press conference was held at the headquarters of the Chilean Medical Association.

I wish to stress that at all times I was received with deference and kindness by all those with whom I met. Perhaps this can be attributed to the fact that I was announced as the representative of more than two million free and independent doctors not connected with any communist country and to the excellent liaison work done by the Belgian Foreign Affairs department, the Belgian ambassador in Santiago, and the Chilean ambassador in Brussels.

In Chile I met with:

—Alberto Cardemil, under-secretary of Internal Affairs, known as the Government's key man in repression activities against the opposition;

—Hugo Rosende, Minister of Justice and personal friend of Dr. L Gonzalez;

—Dr. Winston Chinchon, Minister of Health, and his chief of staff, Dr. Ricardo Caram;

—Rafael Retamal, president of the Supreme Court;

—Judge German Valenzuela Erazo, President of the court in charge of the affair and responsible for the final ruling;

—Professor Amador Neghme, President of the Academy of Medicine;

—Monsignor Sergio Valech, Ausxiliary Bishop, leader of Catholic action in the country.

From these meetings, I gathered that the lawyers had

not petitioned for the prisoners to be released on bail. Therefore, during my meeting with Judge Valenzuela, I officially presented a request for the release of Drs. Gonzalez and Rivas, pledging the moral guarantee and support of the two million physicians represented in the WMA.

I was authorised to inform the Chilean government that in the event these two collegues were convicted, Belgium and I, myself—as well as the University of Louvain, represented by its Rector, Monsignor Massaux—were ready to grant them asylum if their sentence were commuted to exile, which the Chilean government would be willing to consider. If so, the Belgian government would permit them to practise in Belgium during their exile and under the same conditions as Belgian physicians.

Advised of this possibility, Drs. Gonzalez and Rivas were reluctant on account of their solidarity with the 15 other people arrested for the same reasons. Their lawyers, in the meantime, confirmed their intention of requesting, within the next 48 hours, that the prisoners be released on bail.

A meeting was also held with Dr. Alvaro Reyes and Dr. Ramon Rojas who had spent three months in the same prison as Dr. Gonzalez and Dr. Rivas for failing to report to the police a wounded man they had treated at the Chiloe clinic. They had been released on bail the week before. Two other colleagues, Ramiro Olivares and Juan Macaya, are still in prison on the same charges. They work for Vicaria de la Solidaridad, a Catholic Church human rights organistion in Santiago.

I had the opportunity of visiting las Condes private clinic and El Salvador University Hospital, where I was received by Professor Umberto Reyes, Head of the Internal Medicine Service. There is an indescribable contrast between the luxury of the clinic and the meagerness of the hospital, which is so deprived of the most essential equipment and personnel that it has been forced to close some of its departments for lack of resources.

The enormous discrimination between medical care available to the rich and to the poor raises a serious ethical problem and is unquestionably conducive to considerations of euthanasia motivated by a total lack of medical care for the poor.

All physicians encountered, from heads of departments to medical students and residents, unanimously denounced this situation which they consider an unacceptable breach of human rights. They expressed their moral discontent by actively supporting the opposition and by their solidarity with Dr. Gonzalez and Dr. Rivas and the National Civic Assembly they had helped to create and which they diligently direct.

As mentioned, the visit ended with a press conference during which an objective report was presented on what had been done in Santiago. Special emphasis was gives to the total independence and apolitical attitude with which the assignment had been accomplished. The support received in Belgium and the assistance given by Belgian diplomatic circles, the Chilean Medical Association, temporarily presided over by Dr. Acuna, the Chilean Academy of Medicine, the Universities, and the Catholic Church were duly acknowledged and appreciated. Recognition was given to the Chilean authorities and judiciary for their understanding. Obviously, they were impressed by the World Medical Association's moral prestige and the strength it represents. I said that I hoped Chilean justice would take into consideration the detainees' moral and professional values, which no one I met questioned at any time. In conclusion, I would like to note how impressed I was by the enormous contrast in Chile between, on the one hand, the serious government action against the basic principles of medical ethics and human rights—the latter now under review by a commission headed by the department of the interior and a group of jurists and lawyers—and, on the other hand, the great freedom enjoyed by a vigorous opposition press, the freedom of opponents to express themselves against the regime, and the absence of border control mesures.

No entry or exit visa was required, and luggage was not searched at any time. Neither was this an exception because of the special nature of my trip. The rules are identical for all travellers, and this was confirmed by colleagues in the Chilean Medical Association. Nobody was able to explain whether this contrast should be interpreted as a strength or weakness of the government.

On August 19, I was informed that Drs. J. L. Gonzalez and F. Rivas had been released on bail that day and authorised to stay in Chile. Drs. Ramiro Olivares and Juan Macaya were also released for days after my visit to Santiago. The Minister of Health, Dr. Chinchon, was dismissed from his functions in the government a few days after my visit.

Correction

In the June 1988 issue please note the following correction in Health Care, Health Policy and Underdevelopment in India by Ravi Duggal. On page 17 the sentence beginning 'The fact is that Britain's... should read: The fact is that Britain's and USA's state health expenditure was equivalent to India's national income and their health care facilities between 30 to 40 times more than India. This gap is even worse today. In 1984 health expenditure in the USA was $ 1,580 per capita per year out of which state expenditure accounted for 41 per cent.

On page 20, the sentence beginning 'The budget skyrocketed' should read. The budget skyrocketed from a mere Rs 2.2 crore to Rs 25 crore in the third plan.

The title of table 1 should read Growth of Health Infrastructure and Investment in India. The figures in brackets in column 2 refer to private hospitals and in column 5, rural beds

Action Against Doctors Involved in Torture

francisco rivas larrain

In 1982 with the institution of free elections to the Colegio Medico de Chile which was charged with ethical supervision of the profession, there has been much reorganisation and a new code of ethics has been prepared and is implemented vigorously despite opposition from the political authorities.

TORTURE has been practised in Chile systematically and continuously since the coup of 1973. There is sufficient evidence that those responsible for torture in Chile are the security institutions of the armed forces, the police, and the government security agencies: first Direction de Inteligencia Nacional (DINA), followed by Central National de Informaciones (CNI) to the present time. Thousands of cases of torture perpetrated by the above institutions have been documented and denounced by Church and human rights organisations, professional colleges, and international institutions.

In Chile, the armed forces have always included physicians, civilians as well as those with military rank. Until 1973, however, military doctors were shown the same respect as other doctors and were not burdened with the suspicions which are now cast upon them.

During the dictatorship, over 80 physicians directly or indirectly participated in acts of all-treatment, humiliation, or torture; the great majority of these physicians belonged to the armed forces and were attached to the security agencies.

From 1973 to 1982, the officers of Colegio Medico de Chile were appointed by the military authorities. Servile and obedient, these officers heard reports of physicians participating in acts of torture but did nothing to investigate or denounce them.

In 1982, the government enacted a new law on professional colleges, whereby the organisation of more than one college was permitted and authority of the Colegio Medical de Chile for ethical supervision of its members was revoked. Simultaneously, the law allowed free elections to be held in the Coliegio. The pro-Pinochet, prodictatorship position was defeated at these elections, and the officers elected fully represented the opposition.

The Colegio's new authorities set themselves three major lines of action:

(1) Defense and protection of physicians against abuse from the Ministry of Health and optimisation of the Solidarity and Welfare of Departments of the Colegio Medico.

(2) Defence of Chilean public health. Criticism of and mobilisation against those health laws which the government seeks to impose which are arbitratry and elitist, beneficial to higher- income sectors. Report of poor conditions for medical service and near-irreparable deterioration of the Chilean hospital system, which until 1973 was a model of high quality and efficiency.

(3) Struggle to defend, protect, and encourage human, social, and political rights of physicians and all citizens of this country.

This last item has evoked the vigorous, undeviating will of the Colegio Medico to investigate the part played by doctors in all forms of violation of human rights, especially torture.

Since the democratic election of its officers, the General Council of the Colegio Medico has reorganised its Department of Medical Ethics and set up a Human Rights Committee.

From their inception, these departments began to receive reports of the participation of doctors in acts of torture. These reports have been divided into cases where evidence is obtainable and cases which, though undoubtedly true, lack conclusive proof for an investigation. All these reports have been received by the General Council of the Colegio Medico through the regional councils across the country, channelled by the Ethics Department and the Human Rights Committee.

To date, two cases involving four physicians have been investigated and tried; two of the doctors were suspended from the Colegio for one year, the other two were expelled. In addition a trial of another three doctors responsible for the death from torture inflicted by members of the security agencies in a northern city is reaching its final stage.

In the first two cases, the accused were found guilty of negligence in the medical examination of individuals under arrest who were subsequently tortured; various extenuating circumstances were taken into account. In the other two cases, most serious breaches of ethics including negligence in medical examination, wilful omission in reporting lesions, insufficient and unreported treatment of torture victims, issuing false health certificates, together with the absence of extenuating circumstances, deserved the sentence of expulsion from the Colegio Medico.

The above trials were conducted impartially and impeccably by the General Council of the Colegio Medico which is its highest court with renowned counsel acting for the defence of the accused. All counsel, including counsel for the defense of the doctors expelled from the college, agreed that the medical court had shown exemplary fairness and impartiality. Furthermore, not only have the Chilean public opinion and the international

medical community (World Medical Association) acknowledged the same merits, but also the entire body of Chilean physicians have recognised the fair-mindedness of the General Council in dealing out justice and in its generosity towards the culprits.

However, the efforts of the Colegic Medico in this area did not stop there. A new code of ethics was prepared and drafted. At the preliminary meeting held recently in Montevideo to restore the Federation of Medical Associations of Latin America, this code was taken as a model for a continental Code of Medical Ethics.

Our efforts are known beyond our frontiers; we have reported on them before, as we are doing today, with both pride and shame: With pride, because in the midst of cruel dictatorship we have been able to denounce and punish the henchmen of terror and death; with shame, because the men we have tried are physicians, Chilean physicians who had taken the Hippocratic oath and made a commitment to life, not death. Neither is our fight for human rights framed within the bounds of medical ethics. Since we know that we are citizens before being doctors and that human and political rights are best protected in a democracy, we are also involved in the political struggle against the regime.

We say this with pride. The Colegio Medico de Chile penalises physicians who practice torture and strives actively to put an end to Pinochet's dictatorship. We are members of the Asamblee de la Civilidad de Chile, which embodies the 22 most representative social organisations in the country (blue-collar workers, rural workers, slum-dwellers, professional men and women, students, women, university academics, ethnic minorities, and others), and we are part of the plan for progressive civil disobedience designed to put an end to dictatorship. We have been jailed for it, and this we also declare with pride.

In Chile, physicians who practise torture are promoted in the armed forces; we doctors who denounce torture within the military circle of dictatorship are thrown into the jails of Pinochet. Unamuno spoke of peoples with a tragic sense of life. Of men who share this tragic feeling—the feeling that leads a man or a people to folly in the pursuit of freedom. Such folly is ours. To try a torturer under a regime with torture as its policy is folly. To foster civil disobedience under a regime that believes in sterlie order and vertical authoritarianism is further folly. To be jailed under a dictatorship that tortures and murders unhindered is folly, too.

We love such folly. It is the folly of Bolivar, Carrera, Manuel Rodriquez, and Salvador Allende: The sublime, heroic folly that made our peoples free. The heritage that allows us to know we are free and to continue struggling for final liberation of our country. We Chilean physicians know that the solidarity of Danish physicians and physicians all over the world is behind us. That is one of the strongest support in our struggle. We will put an end to torture when we recover democracy. Our victory will be your victory too.

[This presentation was made at the International Meeting on Doctors, Ethics and Torture in Copenhagen by Professor Bent Sorensen on behalf of Dr. Francisco Rivas Larrain, who had been imprisoned by the authorities in Chile on unspecified charges.]

Economic and Political Weekly

A journal of current affairs, economics and other social sciences

Every week it brings you incisive and independent comments and reports on current problems plus a number of well-researched, scholarly articles on all aspects of social science including health and medicine, environment, science and technology, etc.

Some recent articles:

Mortality Toll of Cities—Emerging Pattern of Disease in Bombay: Radhika Ramsubban and Nigel Crook

Famine, Epidemics and Mortality in India—A Reappraisal of the Demographic Crisis of 1976-78: Ronald Lardinois

Malnutrition of Rural Children and Sex Bias: Amartya Sen and Sunil Sengupta

Family Planning and the Emergency—An Unanticipated Consequence: Alaka M Basu

Ecological Crisis and Ecological Movements: A Bourgeois Deviation?: Ramachandra Guha

Environment Conflict and Public Interest Science: Vandana Shiva and J Bandhyopadhyay

Geography of Secular Change in Sex Ratio in 1981: Ilina Sen

Occupational Health Hazards at Indian Rare Earths Plant: T V Padmanabhan

Inland Subscription Rates

Institutions/Companies one year Rs 325, Two years Rs 625, Three years Rs 925

Individuals Only: One year Rs 250, Two years Rs 475, Three years Rs 700

Concessional Rates (One year): Students Rs 150; Teachers and Researchers Rs 200
(Please enclose certificate from relevant academic institution)

[All remittances to **Economic and Political Weekly,** 284, Hitkari House, Shahid Bhagatsingh Road, Bombay 400 038. Payment by bank draft or money order preferred, Please add Rs 14 to outstation cheques for collection charges.]

A cyclostyled list of selected articles in EPW on health and related subjects is available on request.

Press Reports on Human Rights Violations in India

A Tiny Sample Study

ALERT citizen's groups in many places over the world have contributed much to exposing human rights abuses by state organs and to biases in reporting through forming 'media watch' groups. The idea is to carefully scan media reports and, (as somewhat we have done here) classify the data collected. Such scanning also clearly highlights policy biases in reportage by government-controlled or other partisan media.

In order to make a small random study of press-reports on human rights violations, we turned to two files maintained by the Centre for Education and Documentation Bombay, one on police atrocities/encounters/combing operations/brutality and the other on 'civil liberties/democratic rights/infringements/organisations/enquiries etc'. There were no direct reports on specific instances of violation in the second category for the period we looked up: July-September 1988. The first file yielded 32 items from nine major dailies and five magazines. We did an exercise on classifying these reports in two ways i)statewise and ii)by type of human rights violation—an arbitrary but marginally useful exercise.

What we drew from our classification is as follows: 8 reports from Maharashtra (2 from Bombay but most others also from areas nearby), 3 from Orissa, 2 from Bihar and UP and 1 each from Delhi, Gujarat, Karnataka, Nagaland, Punjab, Rajasthan and West Bengal. (4 items were 'repeat' reports not counted here and 3 not clear). Three reports covered the whole country. (Of course, it must be pointed out that at CED we receive more dailies from Bombay than anywhere else. Hence perhaps the large number of instances reported for Maharashtra).

The 'type of human right violation' exercise yielded the following results:

1. Torture/death in lockup	6
2. Police beatings/assault	5
3. Illegal arrests/detention/seizure	4
4. Marauding, terrorisation, oppression of depressed sections	3
5. Direct killing/shooting	2
6. False encounters	3
7. Sexual abuse (including gangrape)	3
8. Framing false charges	2
9. General reports on human rights abuse on state/nation basis.	5

(one report has been counted under both 3 and 7).

Scanning these reports, there seem to be two major categories of 'motives' for these acts. In half the cases, the victims have clearly been earmarked for political repression through the use of violence (and abuse of machinery that is supposedly meant to protect the rights of common citizens). Roughly another half are simply victims of the police machinery blatantly overstepping its brief: either out on a drunken, marauding spree or unleashing calculated brutality against weak, marginalised sections and/or person(s) who have in some way (sometimes unwittingly) exposed the weaknesses in the state machinery.

R R

(Cont. from page 64)

but were not. He was, however, examined in 1966 and found to be sane. Yet he rotted in jail. In 1981 after news of his detention was published in a newspaper he was once again mentally examined and found to be sane. He was released in 1983 almost 35 years too late.

Like Gomia-Ho there were cases of many other prisoners who were kept in jail as the mental hospitals were full.

In *Charles Sobhraj's* case (1978, 4.SCC.494) the prisoner was kept day and night under bar fetters. The doctor examining the prisoner had noted:

> 09.2.1977: Multiple infected wounds on right ankles. Bar fetters be removed from right leg for 15 days (Sd) Dr. Mittal R.M.O.
>
> 12.2.1977: Bar fetters also to be removed from left foot. (Sd) Dr Bokra.

The supreme court severely restricted the use of bar fetters and condemned their generalised and indiscriminate use. Case of torture in police lock-ups and prisons are routine and endemic. The role of doctors in this is dubious. They are mainly used for cover up purposes.

Appeal to Subscribers/Readers

We regret that the last few issues of the *Radical Journal of Health* have been delayed. This has been because of printing and other difficulties, none of which fortunately are insurmountable. We hope to bring the publication up-to-date in the next couple of months. Please bear with us!

The RJH is for you and is sustained mainly by the support of regular readers like you. So far the journal is being subsidised by donations from concerned individuals. We would not like to pass on the burden of the extra cost to our readers by increasing the subscription rates. The Socialist Health Review Trust, the publisher of RJH has started a campaign for creating a corpus fund which can continue to absorb the extra cost as far as possible.

We appeal to you and your friends to generously contribute to this fund. *All donations may be made payable to the Socialist Health Review Trust and are exempted from Income Tax under Section 80G of the Income Tax Act.*

Torture, Psychiatric Abuse and Health Professionals

r raghav

The Breaking of Bodies and Minds: Torture, Psychiatric Abuse and the Health Professioanals Edited by Eric Stover and Elena Nightingale, The American Association for the Advancement of Science/WH Freeman and Co., New York, 19855; pp 320.

THE book is a result of a symposium sponsored by the Committee on Scientific Freedom and Responsibility (CSFR) of the American Association for Advancement of Science (AAAS) in January 1981 on the subject. Through case history and analysis, the contributors examine the role of health professionals, (HPs) in the use and prevention of torture and psychiatric abuse (TPA) "in the context of the political, social and ethical forces that guide their actions". It addresses itself to such questions as—how and why HPs participate in serious violations of human right; what are the conditions under which such violations occur; and what can organisations of HPs, scientists and others do to check the trend.

As the book notes, "violations of human rights have become so well-organised, so systematic, so efficient, that it is now a kind of industry". Through careful documentation of abuse and lucid insights into the dilemmas of HPs and others working under repressive governments the book presents a clear delineation of the ethical issues involved. In the final chapter, the editors suggest organised monitoring, protest and action through professional associations to counter state-sanctioned routinisation of TPA for political purposes. To quote from the foreward, "It is now more urgent than ever that we use the extraordinary human capacity for learning, communications, and attachment to one another to foster the bonds of mutual respect".

Apart from sporadic misuse of authority or isolated abuses resulting from poor practice/lack of proper resources, TPA as a systematic means of political control are prevalent in at least 66 (nearly one-third) of the world's nations, notes the book. In this, HPs are collaborators in misuse of medicine, mis-certification of victims and other forms of flagrant and deliberate abuse of professional ethics. Alarmingly, "These collaborators in abuse are not simply mad doctors... satisfying their own sadistic desires; they include apparently normal HPs".

Extent definitions of torture are reviewed and their common features noted. In essence, torture is the deliberate infliction of pain by one person on another to break down the will of the victim. The degree of abuse that constitutes 'torture' sometimes needs clarification—for example, solitary confinement, in itself, is not torture under international law. TPA may include physical, psychological and pharmacological and psychiatric abuse forms. However, all torture invariably produces psychological distress in the victim.

Some Testimonies

"I realised that pain can always increase without end. To have that feeling is devasting for the mind. Absolute loneliness and endless time are abstract ideas... but when experiencing them, the desperation is hard to describe".

"The entire affective world... collapses with a kick in the father's genitals, a smack on the mother's face, an obscene insult of the sister, or the sexual violation of a daughter. Suddenly an entire culture based on familial love, devotion, the capacity for mutual sacrifice, collapses. Nothing is possible in such a universe, and that is precisely what the tortures know".

"It is hard to be a survivor. It is hard to remember and tell this story, but I reappeared because people worked... Now I cannot let the others down".

Widespread Prevalence

Apart from its routine employment in war, torture is now being increasingly sanctioned by governments against peacetime 'subversion'. This form of official sanction is often combined with suspension of basic human rights and legal procedures; or else executed through quasi-governmental 'intelligence' groups over which direct government responsibility is disclaimed. Another alarming factor is the emergence of clear military/police training programmes on 'interrogation techniques', such as at the International Police Academy of the Agency for International Development at Washington, DC.

The book mentions cases of torture reported from the Algerian War (French), Vietnam War (by all parties), El Salvador, Guatemala, Indonesia; 'disappearances' and torture are reported from Afghanistan, Argentina, Bolivia, Burundi, Cambodia, Central African Empire, Chile, East Timor, Ethiopia, Iran, Peru, Philippines, Syria and Uganda. References to psychiatric abuse (PA) in Rumania, Uruguay, USA, Japan and USSR (which has been particularly indiated) are included; as well as documented involvement of HPs in abuse in Rome, Japan, Chile, Mauritania, Portugal, Sudan, Iran, Greece, USA and

USSR. Cases of conflict between HPs and governments and the issue of putting to practice codes of medical ethics have been considered from Chile, Uruguay, Brazil and South Africa. The book, however, distinctly focuses on physical abuse in Latin America and psychiatric abuse in USSR... because abuse is particularly widespread, systematic and well-documented in them".

Compiled evidence indicates that the role of HPs may include: Medical examinations at various stages: Attendance at torture sessions to intervene when the victim's life is threatened; treatment and 'patch-up' of injuries; development/refining of torture techniques and sometimes, administration of torture; and false certification of subjects for various reasons.

The participation of HPs in TPA clearly violates three basic tenets of medical ethics: (1) To do more good than harm; (2) To intervene only when the patient is willing and (3) To render treatment regardless of political or other considerations. This disregard of medical ethics cannot be justified in moral terms as serving any higher social purpose, as the book clearly shows through consideration of the commonly applied principles of justice, benevolence and autonomy.

The utilitarian argument for torture sanctions its limited use if it produces more good than evil; such as, say, against terrorists who may destroy hundreds of innocent lives. Such a position is difficult to achieve in practise, as its inefficiency and inefficacy have been regularly remarked up on. The 'good' result is a hypothetical probability, often not realised. More importantly, the applicability of such a rule is not clear. Known terrorists must be tortured. Can we torture their family, friends, neighbours, uncertain acquaintances? Clearly, the good that may be achieved is dwarfed by the evils imposed by a state-sanctioned system, which brutalises many ordinary people wielding some power—army, police, 'intelligence' people; associated medical and legal people, administrators—and corrodes the roots of civilised society.

One argument the book seems to have missed is regarding the context in which such a utilitarian argument is propounded—as a dubious means towards unworthy ends. 'Subversion', 'dissent', 'terrorism', 'war'—these are usually the result of an unsatisfactory political system—and the right thing to address would be the correction of this cause, rather than the sanction of a new evil in support of the one existing.

Research indicates that some torture victims suffer symptoms similar to concentration camp survivors and prisoners of war ((POWs): long-term physical and emotional trauma-heightened anxiety, recurrent nightmares, phobias that sometimes require counseling and treatment. It is also apparent that emotional problems increase on the torture victims emigrating to a new country and culture. Accounts of torture victims remind us that brutality can never be comprehended or measured in the abstract. It is a succession of personal tragedies, disabling to the individuals involved and destructive to humankind.

HPs, employers and other persons who interact with victims of torture need to be aware of and understand the consequences of TPA on the life of victims who will otherwise continue to be victims of misdiagnosis, inappropriate medical and psychiatric care, of preventable job stress and discrimination, of marital and family disruption, and of avoidable suicide.

The book outlines two studies on former torture victims—one covering 44 persons now settled in seven cities of the USA, the other 41 people in Toronto. Standard research protocols for physical and psychological evaluation were established. Those, and other similar studies, indicate a broadly consistent range of after effects in the majority of victims; objective evidence of physical damage in inverse proportion to the period of time elapsed; more widespread long-term psychological disturbances ranging from nervousness to post-traumatic stress disorder. Therefore, many psychologists argue for the establishment of specific diagnostic criteria for a 'torture syndrome'. While this will prevent the overlooking of the psychological difficulties of the victims, other psychologists argue that this might also result in labelling and stigmatisation of victims, particularly those who have come to terms with their experiences.

The book outlines criteria for provision of appropriate psychiatric service—underscoring the importance of rebuilding trust in human values, expunging 'situational guilt', assisting in the victims 'struggle for meaning', and cushioning the effects of rehabilitation into a new society and culture.

Psychiatric Abuse in USSR

Doubtless, PA is employed by intelligence agencies, particularly military, the world over. The book examines in detail the various factors (and the capability of HPs) that have led to the existence of a seemingly institutionalised system in the USSR.

Psychiatric internment for political purposes in Russia started somewhere in the 1930s. It gathered political sanction during the Khruschev period. A series of scandals in the 1970s resulted in worldwide concern and debate, culminating in the bowing out of the Soviet body, the All-union Society, from the World Psychiatric Association (WPA) in January 1983. (The society has recently been re-admitted to the WPA). However, there has been concern that while admitting maladministration of psychiatric care, the USSR has detracted attention from its political misuse, which is probably bound to continue. While many political victims have been freed from psychiatric prisons and there has been an announcement that all other political prisoners would be released from jail (*Indian Post*

October 27 1988, p 1) there is evidence of new cases of internment during the past two years.

Some psychologically healthy dissenters and human rights (HR) activists in the USSR are labelled mentally ill and subject to compulsory hospitalisation and 'treatment'. It is argued that the Soviet approach to psychiatric diagnosis, particularly the concept of schizophrenia, is a critical factor in labelling dissent as mental illness. Such activity is not simply conformance to the prevailing political system by one sympathetic part of the health bureaucracy. It would appear that psychiatric theory and practise have been systematically bent in the USSR for this purpose—a large-scale, cross-cultural WHO study showed that Soviet psychiatrists have a broader concept of schizophrenia and a unique system of categorisation that differs from that of other psychiatrists worldwide. The Sovieztinevsley school which dominates Soviet psychiatry is "... characterised by extremely broad diagnostic criteria, extreme schematism in classification and overwhelming pessimism in prognosis". It postulates that schizophrenia is genetic in origin, irreversible and deep-seated.

The forensic (legal) implications of the Soviet view are also far-reaching. It states that "schizophrenia is a disease in which patients are, with rare exceptions, deemed not responsible (for their behaviour)". Further, with the extremely broad conception of the disease, it is possible that the defendant, who is normal on examination, is still harbouring severe illness.

State-sanctioned torture can become a malignancy of the body-politic. The political system, professional group, public opinion and individual values—these establish norms of conduct, and normally these norms do not conflict. The fact that professionals face dilemmas when conflict occurs underscores the importance of developing ethical standards. An epidemiolocal approach, such as exists in the form of a national network in the US to study the social 'causation' and medico-social implications of murder, is suggested.

Since the people who stand to benefit from TPA are usually those in political positions to sustain it; preventive strategies must be aimed at those in power. Protection of human right is based on three methods: pressure by the international community; actions by national judicial system; and enforcement by international or regional bodies (such as the UNHCR).

Governments bear the 'shame of exposure'. Systematic collection of information by national groups is important. The International Committee of the Red Cross (ICRC) has probably the most detailed information worldwide; visiting prisoners worldwide to check on detention conditions as specified in the Geneva Convention. The International Medical Commission for Health in Human Rights (Geneva) could probably coordinate a data network on epidemiology, suggest the editors in their concluding chapter.

Research on how and why reasonably normal people get co-opted into perverse practises is also important. R.J. Lifton has suggested that one of the key concepts underlying Nazi medical killings was belief in the legitimacy of destroying 'life unworthy of life'. Lifton suggests that the Auschwitz doctors sometimes experienced ethical conflicts but were able to resolve them through a process of 'doubling'—creating an 'Auschwitz self' as well as a humance-husband father self—even as they killed, they held on to the idea that they were healers.

Medicine has become part of society's explicit political response to the general predicament of humans. Medicine is now an institutionalised social instrument employed for the general political purposes of the community—regulating birth and mortality rates, controlling epidemics, etc. In the circumstances, HPs have a positive duty to protect its ethical tenets. As the book states—we are now technically capable of treating bodies and minds effectively on a large scale. To put Orwell's fears of 1984 behind us, we must put medical ethics and internationally defined human right in front of us.

(Cont. from page 67)

Concerning the erroneous demand of 'loyalty', in *Rafael Bielsa's* book *La funcion publica*, (Ed, Depalma, Buenos Aires, 1960, p. 34.) (Public duties) we read as follows: "The meaning of collaborating in public administration is not that of a partnership where everything must be accepted and legitimised. On the country, it implies checking, revision, objections, observations, and even well-founded opposition to any illegal or inappropriate act contrary to public interest." All professions should have a certain autonomy enabling them to resist pressures from the political systems in which they operate.

Finally, let us be united in our intentions and as physicians recall this statement from the Declaration of Geneva: "I will maintain the utmost respect for human life from its beginning even under threat and I will not use my medical knowledge contrary to the laws of humanity."

Let this be poignantly rooted in our consitences so that society and all its institutions and organs can not accept the practice of torture in their midst ever to happen again. Likewise, let it no longer be allowed that physicians alienated from their medical standards act as unconscious robots for the military in prower. *Let us under no circumstances whatsoever permit the existence of statutes, enclaves, or hierarchies that engender posibilities for such barbarity.*

Human Rights Ethical Codes and Declarations

A. Statements by Professional Associations

(i) The World Medical Association (WMA)

Resolution on Physician Participation in Capital Punishment

Following concern about the introduction of an execution method (lethal injection) which threatened to involve doctors directly in the process of execution, the WMA Secretary-General issued a press statement opposing any involvement of doctors in capital punishment. The 34th Assembly of the WMA, meeting in Libson some weeks after the issuing of the press statement, endorsed the Secretary-General's statement in the following terms:

Resolved, that the Assembly of the World Medical Association endorses the action of the Secretary General in issuing the attached press release on behalf of the World Medical Association condemning physician participation in capital punishment.

Further resolved, that it is unethical for physicians to participate in capital punishment, although this does not preclude physicians certifying death.

Further resolved, that the Medical Ethics Committee keep this matter under active consideration.

Secretary General's Press Release

The first capital punishment by intravenous injection of lethal dose of drugs was decided to be carried out next week by the court of the state of Oklahoma, USA.

Regardless of the method of capital punishment a state imposes, no physician should be required to be an active participant. Physicians are dedicated to preserving life.

Acting as an executioner is not the practice of medicine and physician services are not required to carry out capital punishment even if the methodology utilizes pharmacological agents or equipment that might otherwise be used in the practice of medicine.

A physician's only role would be to certify death once the State had carried out the capital punishment.

September 11, 1981

Regulations in Time of Armed Conflict

These regulations or guidelines set out the WMA's standards on the medical ethical position of the physician during a period of war or other armed conflict. The statement was approved by the 10th World Medical Assembly in Havana in 1956, was edited by the 11th Assembly meeting in Istanbul the following year and was amended by the 35th World Medical Assembly in 1983.

The ameded text reads as follows:

1. Medical ethics in time of armed conflict is identical to medical ethics in time of peace, as established in the International Code of Medical Ethics of the World Medical Association. The primary obligation of the physician is his professional duty; in performing his professional duty, the physician's supreme guide is his conscience.

2. The primary task of the medical profession is to preserve health and save life. Hence it is deemed unethical for physicians to:

A. Give advice or perform prophylactic, diagnostic or therapeutic procedures that are not justifiable in the patient's interest.
B. Weaken the physical or mental strength of a human being without therapeutic justification.
C. Employ scientific knowledge to imperil health or destroy life.

3. Human experimentation in time of armed conflict is governed by the same code as in time of peace; it is strictly forbidden on all persons deprived of their liberty, especially civilian and military prisoners and the population of occupied countries.

4. In emergencies, the physician must always give the required care impartially and without consideration of sex, race, nationality, religion, political affiliation or any other similar criterion. Such medical assistance must be continued for as long as necessary and practicable.

5. Medical confidentiality must be preserved by the physician in the practice of his profession.

6. Privileges and facilities afforded the physician must never be used for other than professional purposes.

Rules governing the care of sick and wounded, particularly in time of conflict

A. 1. Under all circumstances, every person, military or civilian must receive promptly the care he needs without consideration of sex, race, nationality, religion, political affiliation or any other similar criterion.
2. Any emergencies, physicians and associated medical personnel are required to render immediate service to the best of their ability. No distinction shall be made between patients except those justified by medical urgency.

B. 1. In emergencies, physicians and associated medical personnel are required to render immediate service to the best of their ability. No distinction shall be made between patients except those justified by medical urgency.
2. The members of medical and auxiliary professions must be granted the protection needed to carry out their professional activities freely. The assistance necessary should be given to them in fulfilling their responsibilities. Free passage should be granted whenever their assistance is required. They should be afforded complete professional independence.
3. The fulfillment of medical duties and responsibilities shall in no circumstances be considered an offence. The physician must never be prosecuted for observing professional secrecy. In fulfilling their professional duties, the medical and auxiliary professions will be identified by the distinctive emblem of a red serpent and staff on a white field. The use of this emblem is governed by special regulation.

Declaration of Tokyo

The Declaration of Tokyo has, since its adoption in 1975, been the most comprehensive statement produced by the medical profession on the question of the torture and cruel, inhuman or degrading treatment of detainees. It was adopted by the 29th World Medical Assembly, Tokyo, Japan.

The rest is as follows:

It is the privilege of the medical doctor to practise medicine in the service of humanity, to preserve and restore bodily and mental health without distinction as to persons, to comfort and to ease the suffering of his on her patients. The utmost respect for human life is to be maintained even under threat, and no use made of any medical knowledge contrary to the laws of humanity.

For the purpose of this Declaration, torture is defined as the deliberate, systematic or wanton infliction of physical or mental suffering by one or more persons acting alone or on the orders of any authority, to force another person to yield information, to make a confession, or for any other reason.

1. The doctor shall not countenance, condone or participate in the practice of torture or other forms of cruel, inhuman or degrading procedures, whatever the offence of which the victim of such procedures is suspected, accused or guilty, and whatever the victim's beliefs or motives, and in all situations, including armed conflict and civil strife.

2. The doctor shall not provide any premises, instruments, substances or knowledge to facilitate the practice of torture or other

forms of cruel, inhuman or degrading treatment or to diminish the ability of the victim to resist such treatment.

3. The doctor shall not be present during any procedure during which torture or other forms of cruel, inhuman or degrading treatment is used or threatened.

4. A doctor must have complete clinical independence in deciding upon the care of a person for whom he or she is medically responsible. The doctor's fundamental role is to alleviate the distress of his or her fellow men, and no motive whether presonal, collective or political shall prevail against this higher purpose.

5. Where a prisoner refuses nourishment and is considered by the doctor as capable of forming an unimpaired and rational judgment concerning the consequences of such a voluntary refusal of nourishment, he or she shall not be fed artificially. The decision as to the capacity of the prisoner to form such a judgment should be confirmed by at least one other independent doctor. The consequences of the refusal of nourishment shall be explained by the doctor to the prisoner.

6. The World Medical Association will support, and should encourage the international community, the national medical associations and fellow doctors, to support the doctor and his or her family in the face of threats or reprisals resulting from a refusal to condone the use of torture or other forms of cruel, inhuman or degrading treatment.

(ii) World Psychiatric Association (WPA)

Declaration of Hawaii

In early 1976 work commenced on the drafting of an international code of thics for psychiatrists which was subsequently adopted in 1977 at the VI World Congress of Psychiatry in Honolulu, Hawaii. At the same meeting the WPA committed itself to receive and investigate allegations of the abuse of psychiatry for political purposes; in 1979 the establishment of the Review Committee was finalised and it first met in Paris in February 1980.

The constitutional status of the Review Committee was changed at the VII Congress in Vienna in July 1983 when it was made permanent and had its remit widened.

Minor amendments to the text of the Declaration were agreed at the July 1983 Congress. The text, as amended, reads as follows:

Ever since the dawn of culture, ethics has been an essential part of the healing art. It is the view of the World Psychiatric Association that due to conflicting loyalties and expectations of both physicians and patients in contemporary society and the delicate nature of the therapist-patient relationship, high ethical standards are especially important for those involved in the science and practice of psychiarty as a medical specialty. These guidelines have been delineated in order to promote close adherence to those standards and to prevent misuse of psychiatric concepts, knowledge and technology.

Since the psychiatrist is a member of society as well as a practitioner of medicine, he or she must consider the ethical implications specific to psychiatry as well as ethical demands on all physicians and the social responsibility of every man and woman.

Even though ethical behaviour is based on the individual psychiatrist's conscience and personal judgment, written guidelines are needed to clarify the profession's ethical implications.

Therefore, the General Assembly of the World Psychiatric Association has approved these ethical guidelines for psychiatrists, having in mind the great differences in cultural background, and in legal, social and economic conditions which exist in the various countries of the world. It should be understod that the World Psychiatric Association views these guidelines to be requirements for ethical standards of the psychiatric profession.

1. The aim of psychiatry is to treat mental illness and to promote mental health. To the best of his or her ability, consistent with accepted scientific knowledge and ethical principles, the psychiatrist shall serve the best interests of the patient and be also concerned for the common good and a just allocation of health resources. To fulfil these aims requires continuous research and continual education of health care personnel, patients and the public.

2. Every psychiatrist should offer to the patient the best available therapy to his knowledge and if accepted must treat him or her with the solicitude and respect due to the dignity of all human beings. When the psychiatrist is responsible for treatment given by others he owes them competent supervision and education. Whenever there is a need, or whenever a reasonable request is forthcoming from the patient, the psychiatrist should seek the help of another colleague.

3. The psychiatrist aspires for a therapeutic relationship that is founded on mutual agreement. At its optimum it requires trust, confidentiality, co-operation and mutual responsibility. Such a relationship may not be possible to establish with some patients. In that case, contact should be established with a relative or other person close to the patient. If and when a relationship is established for purposes other than therapeutic such as in forensic psychiatry, its nature must be thoroughly explained to the person concerned.

4. The psychiatrist should inform the patient of the nature of the condition, therapeutic procedures, including possible alternatives, and of the possible outcome. This information must be offered in a considerate way and the patient must be given the opportunity to choose between appropriate and available methods.

5. No procedure shall be performed nor treatment given against or independent of a patient's own will, unless, because of mental illness, the patient cannot form a judgement as to what is in his or her best interest and without which treatment serious impairment is likely to occur to the patient or others.

6. As soon as the conditions for compulsory treatment no longer apply, the psychiatrist should release the patient from the compulsory nature of the treatment and if further therapy is necessary should obtain voluntary consent. The psychiatrist should inform the patient and/or relatives or meaningful others, of the existence of mechanisms of appeal for the detention and for any other complains related to his or her well-being.

7. The psychiatrist must never use his professional possibilities to violate the dignity or human rights of any individual or group and should never let inappropriate personal desires, feelings, prejudices or beliefs interfere with the treatment. The psychiatrist must on no account utilize the tools of his profession, once the absence of psychiatric illness has been established. If a patient or some third party demands actions contrary to scientific knowledge or ethical principles the psychiatrist must refuse to cooperate.

8. Whatever the psychiatrist has been told by the patient, or has noted during examination or treatment, must be kept confidential unless the patient relieves the psychiatrist from this obligation, or to prevent serious harm to self or others makes disclosure necessary. In these cases, however, the patient should be informed of the breach of confidentiality.

9. To increase and propagate psychiatric knowledge and skill requires participation of the patients. Informed consent must, however, be obtained before presenting a patient to a class and, if possible, also when a case-history is released for scientific publication, whereby all reasonable measures must be taken to preserve the dignity and anonymity of the patient and to safeguard the personal reputation of the subject. The patient's participation must be voluntary, after full information has been given of the aim, procedures, risks and inconveniences of a research project and there must always be a reasonable relationship between calculated risks or inconveniences and the benefit of the study. In clinical research every subject must retain and exert all his rights as a patient. For children and other patients who cannot themselves given informed consent, this should be obtained from the legal next of kin. Every patient or research subject is free to withdraw for any reason at any time from any voluntary treatment and from any teaching or research programme in which he or she participates. This withdrawal, as well as any refusal to enter a programme, must never influence the

psychiatrist's efforts to help the patient or subject.

10. The psychiatrist should stop all therapeutic, teaching or research programmes that may evolve contrary to the principles of this Declaration.

(iii) The International Council of Nurses (ICN)

Role of Nurse in Care of Detainees and Prisoners

At the meeting of the Council of National Representatives of the International Council of Nurses in Singapore in August 1975, the following statement was adopted:

Whereas the ICN Code for Nurses specifically states that:

1. "The fundamental responsibility of the nurse is fourfold: to promote health, to prevent illness, to restore health and to alleviate suffering.
2. "The nurse's primary responsibility is to those people who require nursing care.
3. "The nurse when acting in a professional capacity should at all times maintain standards of personal conduct which reflect credit upon the profession.
4. "The nurse takes appropriate action to safeguard the individual when his care is endangered by a co-worker or any other persons;"

and

WHEREAS in 1973 ICN reaffirmed support for the Red Cross Rights and Duties of Nurses under the Geneva Conventions of 1949, which specifically state that, in case of armed conflict of international as well as national character (i.e. internal disorders, civil wars, armed rebellions):

1. Members of the armed forces, prisoners and persons taking no active part in the hostilities

(a) Shall be entitled to protection and care if wounded or sick,
(b) Shall be treated humanely, that is:
— they may not be subjected to physical mutilation, or to medical or scientific experiments of any kind which are not justified by the medical, dental or hospital treatment of the prisoner concerned and carried out in his interest,
— they shall not be wilfully left without medical assistance and care, nor shall conditions exposing them to contagion or infection be created,
— they shall be treated humanely and cared for by the Party in conflict in whose power they may be, without adverse in conflict in whose power they may be, without adverse distinction founded on sex, nationality, religion, political opinion, or any other similar criteria.

2. The following acts are and shall remain prohibited at any time and in any place whatsoever with respect to the above mentioned persons:

(a) violence to life and person, in particular murder of all kinds, mutilation, cruel treatment and torture;
(b) outrages upon personal dignity, in particular humiliating and degrading treatment.

WHEREAS in 1971 ICN endorsed the United Nations Universal Declaration of Human Rights and, hence, accepted that:

1. "Everyone is entitled to all the rights and freedoms, set forth in this Declaration, without distinction of any kind, such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status (Art.2),
2. "No one shall be subjected to torture or to cruel, inhuman or degrading treatment or punishment (Art.5)"; and

WHEREAS in relation to detainees and prisoners of conscience, interrogation procedures are increasingly being employed which result in ill effects, often permanent, on the person's mental and physical health;

THEREFORE BE IT RESOLVED that ICN condemns the use of all such procedures harmful to the mental and physical health of prisoners and detainees; and

FURTHER BE IT RESOLVED that nurses having knowledge of physical or mental ill-treatment of detainess and prisoners take appropriate action including reporting the matter to appropriate national and/or international bodies; and

FURTHER BE IT RESOLVED that nurses participate in clinical research out on prisoners, only if the freely given consent of the patient has been secured after a complete explanation and understanding by the patient of the nature and risk of the research; and

FINALLY BE IT RESOLVED that the nurse's first responsibility is towards her patients, notwithstanding considerations of national security and interest.

Nurse's Role in Safeguarding Human Rights

Responding to requests from national member associations for guidance on the protection of human rights of both nurses and those for whom they care, the Council of National Representatives of the International Council of Nurses adopted the statement given below at its meeting in Brasilia in June 1983.

This document has been developed in response to the requests of national nurses assosiations for guidance is assisting nurses to safegurads their own human rights and those for whom they have professional responsibility. It is meant to be used in conjunction with the ICN Code for Nurses and resolution relevant to human rights. Nurses should also be familiar with the Geneva Conventions and the additional protocols as they relate to the responsibilities of nurses.

The current world situation is such that there are innumerable circumstances in which a nurse may become involved that require action on her/his part to safeguard human rights. Nurses are accountable for their own professional actions and must therefore be clear as to what is expected of them in such situations.

Also conflict situations have increased in number and often include internal political upheaval, and strife, or international war. The nature of war is changing. Increasingly nurses find themselves having to act or respond in complex situations to which there seems to be no clear cut solution.

Changes in the field of communications also have increased the awareness and sensitivity of all groups to those conflict situations.

The need for nursing actions to safeguard human rights is not restricted to times of political upheaval and war. It can also arise in prisons or in the normal work situation of any nurse where abuse of patients, nurses, or others is witnessed or suspected. Nurses have a responsibility in each of these situations to take action to safeguard the rights of those involved. Physical abuse and mental abuse are equally of concern to the nurse. Over or under treatment is another area to watched. There may be pressures applied to use one's knowledge and skills in ways that are not beneficial to patients or others.

Scientific discoveries have brought about more sophisticated forms of torture and methods of resuscitation so that those being tortured can be kept alive for repeated sessions. It is in such circumstances that nurses must be clear about what actions they must take as in no way can they participate in such torture, or torture techniques.

Nurses have individual responsibility but often they can be more effective if they approach human rights issues as a group. The national nurses associations need to ensure that their structure provides a realistic mechanism through which nurses can seek confidential advice, counsel, support and assistance in dealing with these difficult situations. Verification of the facts reported will be an important first step in any particular situation.

At times it will be appropriate for the NNA to become a spokesman for the nurses involved. They may also be required to negotiate for them. It is *essential* that confidentality be maintained. In rare cases the personal judgment of the nurse may be such that other actions seem more appropriate than approaching the association.

The nurse initiating the actions requires knowledge of her own and other's human rights, moral courage, a well thought through plan of action and commitment and determination to see that the

ncessary follow-up does occur. Personal risk is a factor that has to be considered and each person must be use her/his best judgment in the situation.

Rights of Those in Need of Care

Health care is a right of all individuals. Everyone should have access to health care regardless of financial, political, geographic, racial or religious considerations. The nurse should seek to ensure such impartial treatment.

Nurses must ensure that adequate treatment is provided—within available resources—and in accord with nursing ethics (ICN Code) to all those in need of care.

A patient/prisoner has the right to refuse to eat or to refuse treatments. The nurse may need to verify that the patient/prisoner understands the implications of such action but she should not participate in the administration of food or medications to such patients.

Rights and Duties of Nurses

When considering the rights and duties of nursing personnel it needs to be remembered that both action and lack of action can have a detrimental effect and the nursing personnel must be considered accountable on both counts.

Nurses have a right to practise within the code of ethics and nursing legislation of the country in which they practice. Personal safety—freedom from abuse, threat or intimation—are the rights of every nurse.

National nurses assosiations have a responsibility to participate in development of health and social legislation relative to patient's rights and all related topics.

It *is a duty* to have informed consent of patients relative to having research done on them and in receiving treatments such as blood transfusions, anesthesia, grafts etc. Such informed consent is a patient's right and must be ensured.

(iv) Psychologist:

Statement by International Union of Psychological Science

In July 1976, the Assembly of the International Union of Psychological Science unanimously approved the statement of the Executive Committee of the International Union of Psychological Science made in July 1974.

The text is as follows:

The International Union of Psychological Science

which includes national psychological societies of 42 nations from all over the world;

which thus speaks in the name of over 70,000 professional psychologists who, because the subject of their science is behaviour, are particularly concerned with any acts by which individuals in a systematic and deliberate way infringe upon the inviolable rights of human beings, regardless of race, religion on ideology, these rights being guaranteed by the Charter of the United Nations;

and which is concerned with strict observance of professional standards of ethics in the practice of psychology,

therefore makes the following declarations:

It proclaims that no psychologist, in the exercise of his or her professional functions, should accept instructions or motivations that are inspired by considerations that are foreign to the profession; It protests solemnly against any use of scientific data or of professional methods of psychology that impair the above-mentioned rights;

It formally condemns any collaboration by psychologists—whether actively or passively, directly or indirectly—with the above-mentioned aubses, and it urges its members to oppose any abuses of this sort;

It requests each member-society to make certain that it has enacted a code of ethics and to take those actions required by its code against any member guilty of such abuses against human rights; It declares that the Executive Committee of IPUS is ready to support, with all means at its disposal, any action undertaken by a member-society in order to carry out the terms of the present resolution; It recalls the following statement made by its Executive Committee on July 27 1974: "The Executive Committee wishes to make clear that the International Union of Psychological Science denounces vigorously all practices that are contrary to the high level of morality that must regulate the scientific and professional roles assumed by psychologists in modern society."

It welcomes the United Nation's Resolution, adopted by the General Assembly (Third Committee: A/10408; 243rd plenary meeting, December 9, 1975) on the Protection of All Persons from being subjected to Inhuman Treatment.

B. United Nations Declarations and Codes Principles of Medical Ethics

The principles are elaborated within the text of Resolution 37/194 adopted by the United Nations General Assembly, 18 December 1982.

The General Assembly...

Desirous of setting further standards in this field which ought to be implemented by health personnel, particularly physicians, and by government officials,

1. ADOPTS the Principles of Medical Ethics relevant to the role of health personnel, particularly physicians, in the protection of prisoners and detainees against torture and other cruel, inhuman or degrading treatment on punishment set forth in the annex to the present resolution;
2. CALLS UPON all governments to give the Principles of Medical Ethics, together with the present resolution, the widest possible distribution, in particular among medical and paramedical associations and institutions of detention or imprisonment in an official language of the State;
3. INVITES all relevant inter-governmental organisations, in particular the World Health Organisation, and non-governmental organisations concerned to bring the Principles of Medical Ethics to the attention of the widest possible group of individuals, especially those active in the medical and paramedical field.

Principles of Medical Ethics Relevant to Role of Health Personnel, Particularly Physicians, in Protection of Prisoners and Detainees Against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment

Principle 1

Health personnel, particularly physicians, charged with the medical care of prisoners and detainees have a duty to provide them with protection of their physical and mental health and treatment of disease of the same quality and standard as is afforded to those who are not imprisoned or detained.

Principle 2

It is a gross contravention of medical ethics, as well as an offence under applicable international instruments, for health personnel, particularly physicians, to engage, actively or passively, in acts which constitute participation in, complicity in, incitement to or attempts to commit torture or other cruel, inhuman or degrading treatment or punishment.[1]

Principle 3

It is a contravention of medical ethics for health personnel, particularly physicians, to be involved in any professional relationship with prisoners or detainees the purpose of which is not solely to evaluate, protect or improve their physical and mental health.

Principle 4

It is a contravention of medical ethics for health personnel, particularly physicians:

a) to apply their knowledge and skills in order to assist in the interrogation of prisoners and detainees in a manner that may adversely affect the physical or mental health or condition of such prisoners or detainees and which is not in accordance with the relevant international instruments;[2]

b) To certify, or to participate in the certification of, the fitness of prisoners or detainees for any form of treatment or punishment that may adversely affect their physical or mental health and which is not in accordance with the relevant international instruments, or to participate in any way in the infliction of any such treatment or punishment which is not in accordance with the relevant international instruments.

Principle 5

It is a contravention of medical ethics for health personnel, particularly physicians, to participate in any procedure for restraining a prisoner or detainee unless such a procedure is determined in accordance with purely medical criteria as being necessary for the protection of the physical or mental health or the safety of the prisoner or detainee himself, or his fellow prisoners or detainees, or of his guardians, and present no hazard to his physical or mental health.

Principle 6

There may be no derogation from the foregoing principles on any grounds whatsoever, including public emergency.

Notes

1) See the Declaration on the Protection of All Persons from Being Subjected to Torture and Other Cruel, Inhuman on Degrading Treatment or Punishment (General Assembly Resolution 3452 (XXX), annex), article 1 of which states:

1."For the purpose of this declaration, torture means any act by which severe pain or suffering, whether physical or mental, is internationally inflicted by or at the instigation of a public official on a person for such purposes as obtaining from him on a third person information or confession, punishing him for an act he has committed or is suspected of having committed, or intimidating him or other persons. It does not include pain or suffering arising only from, inherent in or incidental to, lawful sanctions to the extent consistent with the Standard Minimum Rules for the Treatment of Prisoners.

2. "Torture constitutes an aggravated and deliberate form of cruel, inhuman or degrading treatment or punishment."

Article 7 of the Declaration States:

"Each State shall ensure that all acts of torture as defined in article 1 are offences under its criminal law. The sale shall apply in regard to acts which constitute participation in, complicity in, incitement to or an attempt to commit torture."

2) Particularly the Universal Declaration of Human Rights (General Assembly resolution 217 A (III), the International Convenants on Human Rights (General Assembly resolution 2200 A (XXI), annex), the Declaration on the Protection of all Persons from Being Subjected to Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment (General Assembly resolution 3452 (XXX), annex) and the Standard Minimum Rules for the Treatment of Prisoners (First United Nations Congress on the Prevention of Crime and the Treatment of Offenders: report by the Secretariat (United Nations publication, Sales No. 1956, IV.4), annex I.A).

C. Amnesty International Declarations

Declaration on Participation of Doctors in Death Penalty 1981

Amnesty International,

Recalling

that the spirit of the Hippocratic Oath enjoins doctors to practise for the good of their patients and never to do harm,

Considering

that the Declaration of Tokyo of the World Medical Association provides that "the utmost respect for human life is to be maintained even under threat, and no use made of any medical knowledge contrary to the laws of humanity",

Further Considering That

the same Declaration forbids the participation of doctors in torture or other cruel, inhuman or degrading treatments,

Noting

the the United Nations Secretariat has stated that the death penalty violates the right to life and that it constitutes cruel, inhuman or degrading treatment,

Mindful

that doctors can be called on to participate in executions by, *inter alia*,

—determining mental and physical fitness for execution,

—giving technical advice,

—prescribing, preparing, administering and supervising doses of poison in jurisdictions where this method is used,

—making medical examinations during executions, so that an execution can continue if the prisoner is not yet dead,

Declares

that the participation of doctors in executions is a violation of medical ethics;

Calls Upon

medical doctors not to participate in executions;

Further Calls Upon

medical organisations to protect doctors who refuse to participate in executions, and to adopt resolutions to these ends.

This declaration was formulated by the Medical Advisory Board of Amnesty International and was adopted by Amnesty International's International Executive Committee on March 12, 1981.

Conference on Abolition of Death Penalty Declaration of Stockholm

The Stockholm Conference on the Abolition of the Death Penalty, composed of more than 200 delegates and participants from Africa, Asia, Europe, the Middle East, North and South America and the Caribbean region,

Recalls That:

The death penalty is the ultimate cruel, inhuman and degrading punishment and violates the right to life.

Considers that:

—The death penalty is frequently used as an instrument of repression against opposition, racial, ethnic religious and underprivileged groups,

—Execution is an act of violence, and violence tends to provoke violence,

—The imposition and infliction of the death penalty is brutalising to all who are involved in the process,

—The death penalty has never been shown to have a special deterrent effect,

—The death penalty is increasingly taking the form of unexplained disappearances, extra-judicial executions and political murders,

—Execution is irrevocable and can be inflicted on the innocent.

Affirms that:

—It is the duty of the state to protect the life of all persons within its jurisdiction without exception,

—Executions for the purposes of political coercion, whether by government agencies or others, are equally unacceptable,

—Abolition of the death penalty is imperative for the achievement of declared international standards.

Declares:

—Its total and unconditional opposition to the death penalty,

—Its condemnation of all executions, in whatever form, committed or condoned by government,

—Its commitment to work for the universal abolition of the death penalty.

Calls upon:

—Non-governmental organisations, both national and international, to work collectively and individually to provide public information materials directed towards the abolition of the death penalty,

—All governments to bring about the immediate and total abolition of the death penalty,

—The United Nations unambiguously to declare that the death penalty is contrary to internatioinal law.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or Marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Medical Technology, Agricultural Development and Health, Health in People's Movements.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication which means that the issue on Medical Technology is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions in **a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Radical Journal of Health and for cheque add Rs. 5, if outside Bombay).

Declaration Against Torture

The Declaration on the Protection of all Persons from Torture and other Cruel, Inhuman or Degrading Treatment or Punishment (Declaration against Torture) was adopted without a vote by the United Nations General Assembly on 9 December 1975. It calls upon states to take effective measures to prevent torture and lists some of the most important safeguards and remedies to be provided. It is one of the most important international documents on torture.

Declaration on Protection of All Persons From Torture and Other Cruel, inhuman or Degrading Treatment or Punishment

The United Nations General Assembly adopted on December 9, 1975 a declaration condemning any act of torture or other cruel, inhuman or degrading treatment as "an offence to human dignity". Under its terms, no state may permit or tolerate torture or other inhuman or degrading treatment, and each state is requested to take effective measures to prevent such treatment from being practised within its jurisdiction.

The Declaration was first adopted and referred to the Assembly by the Fifth United Nations Congress on the Prevention of Crime and Treatment of Offenders, held in Geneva in September 1975. In adopting the Declaration without a vote, the Assembly noted that the Universal Declaration of Human Rights and the International Covenant on Civil Political Rights provide that no one may be subjected to torture or to cruel, inhuman or degrading treatment or punishment.

The Assembly has recommended that the Declaration serve as a guideline for all states and other entities exercising effective power.

The text of the Declaration follows:

Article 1

1. For the purpose of this Declaration, torture means any act by which severe pain or suffering, whether physical or mental, is intentionally inflicted by or at the instigation of a public official on a person for such purposes as obtaining from him or a third person information or confession, punishing him for an act he has committed or is suspected of having committed, or intimidating him or other persons. It does not include pain or suffering arising only from, inherent in or incidental to, lawful sanctions to teh extent consistent with the Standard Minimum Rules for the Treatment of Prisoners.

2. Torture constitutes an aggravated and deliberate form of cruel, inhuman or degrading treatment or punishment.

Article 2

Any act of torture or other cruel, inhuman or degrading treatment or punishment is an offence to human dignity and shall be condemned as a denial of the purposes of the Charter of the United Nations and as a violation of the human rights and fundamental freedoms proclaimed in the Universal Declaration of Human Rights.

Article 3

No state may permit or tolerate torture or other cruel, inhuman or degrading treatment or punishment. Exceptional circumstances such as a state of war or a threat of war, internal political instability or any other public emergency may not be invoked as a justification of torture or other cruel, inhuman or degrading treatment or punishment.

Article 4

Each State shall, in accordance with the provisions of this Declaration, take effective measures to prevent torture and other cruel, inhuman or degrading treatment or punishment from being practised within its jurisdiction.

Article 5

The training of law enforcement personnel and of other public officials who may be responsible for persons deprived of their liberty shall ensure that full account is taken of the prohibition against torture and other cruel, inhuman or degrading treatment or punishment. This prohibition shall also, where appropriate, be included in such general rules or instructions as are issued in regard to the duties and functions of anyone who may be involved in the custody or treatment of such persons.

Article 6

Each state shall keep under systematic review interrogation methods and practices as well as arrangements for the custody and treatment of persons deprived of their liberty in its territory, with a view to preventing any cases of torture or other cruel, inhuman or degrading treatment or punishment.

Article 7

Each state shall ensure that all acts of torture as defined in article 1 are offences under its criminal law. The same shall apply in regard to acts which constitute participation in, complicity in, incitement to or an attempt to commit torture.

Article 8

Any person who alleges that he has been subjected to torture or other cruel, inhuman or degrading treatment or punishment by or the instigation of a public official shall have the right to complain to, and to have his case impartially examined by, the competent authorities of the state concerned.

Article 9

Wherever there is reasonable ground to believe that an act of torture as defined in article 1 has been committed, the competent authorities of the state concerned shall promptly proceed to an impartial investigation even if there has been no formal complaint.

Article 10

If an investigation under article 8 or article 9 establishes that an act of torture as defined in article 1 appears to have been committed, criminal proceedings shall be instituted against the alleged offender or offenders in accordance with national law. If an allegation of other forms of cruel, inhuman or degrading treatment or punishment is considered to be well founded, the alleged offender or offenders shall be subject to criminal, disciplinary or other appropriate proceedings.

Article 11

Where it is proved that an act of torture or other cruel, inhuman or degrading treatment or punishment has been committed by or at the instigationof a public official, the victim shall be afforded redress and compensation in accordance with national law.

Article 12

Any statement which is established to have been made as a result of torture or other cruel inhuman or degrading treatment may not be invoked as evidence against the person concerned or against any other person in any proceedings.

What Ails Medical Education?

GRIEVANCES are being voiced from various platforms against medical education in India for quite some time. Its products, the doctors, are alleged to be found wanting while serving in the rural milieu. The medical curriculum is being blamed for such deficiencies in medical graduates and erudite schemes are being prescribed from time to time. But curiously, the role of medical teachers has eluded the attention of the commentators. That teachers have a profound role on the nature and quality of education goes without saying. This role has been discussed and analysed from various aspects in different forums. The role of medical teachers in medical education, however, has escaped such analysis, presumably because it is taken for granted that there is nothing special to discuss. On the other hand, in the general debate on pay and service conditions of teachers, even during the All India Teachers' strike in 1987, medical teachers were kept, by an apparent consensus, outside the purview of the exercise on the assumption that they are something special. Political authority and officials look upon medical teachers not primarily as teachers, but as doctors first—taking the job of teaching as a secondary one and medical graduates as by products of health care system. Here we will explore the elements which might clarify the role of teachers in medical education. The prevailing picture in West Bengal has served as a model which may differ in many respects from state to state but shares their essential characteristics.

The world of medical education is small. Teachers and students soon become known to each other. An intimate relationship develops between the teacher and the taught in many instances. Thus teachers influence the students not only in their academic life but also in other spheres of life by their personality and behaviour.

The subject of medical education is composed of a number of disciplines each of which being a speciality by itself has its own conclave of functioning. Teachers of each discpline have their separate associations, journals and/or academic forums. At the same time, all disciplines are integrated at the under-graduate level into medicine (MBBS) where teachers of different disciplines have to interact with each other. However, any integrated method of teaching at the under-graduate level has not been evolved as yet. In the post-graduate education, each discipline functions separately.

In the clinical discipline, teachers also act as specialist doctors and consultants, ie they are engaged in treating patients in hospitals attached to the colleges. This has been instrumental in the development of a sustained relationship between the teachers and students. The young doctors with graduate and post-graduate qualifications, enter the world of medical practice and retain their link and relationship with their teachers which is often life-long— the implication being that the teacher-student relationship is extended beyond the boundaries of Alma Mater.

In the earlier days, doctors were inducted into the teaching job in various ways. In government institutions, doctors were appointed as teachers in medical colleges at a ripe age after they had served their due period in non-teaching hospitals spread all over the state. A good number of doctors who acquired post-graduate qualifications, were also offered teaching posts on an honorary basis. In the non-government medical colleges, almost all teachers were on honorary terms or managed to secure a token salary. This honorary system, though advantageous to the employer, had not been resented by the employees. Appointment to a teaching job in a medical college is a very prestigeous position in the medical profession. It brings renown, uplifts status and quickly establishes the teacher in the field of private practice. People look upon medical teachers as the most learned, accomplished and skilful among the doctors; such an attitude works as a one-way ticket to success in private practice. There are, of course, certain grounds for such belief. Medical teachers belonging to clinical disciplines, are daily engaged in the treatment of patients in indoor and outdoor services. They are in a position to experiment with different curative technologies on the hospital patients, perfect them in hospital practice and then apply those technologies profitably in their private practice. Hospital job not only trains the doctor to be a skilful one but also keeps him abreast of continuing developments in the curative technology.

State of Medical Education

Western medicine was imported in India and initially the curriculum and contents of education were necessarily borrowed. Over the years the curriculum underwent many changes and the teaching methods steadily adopted themselves to the Indian reality. A look at this Indian reality will reveal that production of doctors was stepped up rapidly, after independence with a view to expanding the facilities of curative medicine to the largest sections of the people. To employ the increasing number of doctors, state health services underwent rapid expansion; employees state insurance (medical benefit) scheme was launched, and private industrial sector opened up medicare facilities for the employees. In the seventies, the rate of expansion stabilised and a paradoxical situation emerged. It was found that the employment market for doctors was squeezed, opportunities abroad were reduced, the field of private practice turned tremendously competitive, doctors' list in the employment exchange started swelling and junior doctors resorted to agitation for employment. Paripassu, the

largest section of the people, particularly the rural poor remained deprived of the minimum facilities of life-saving curative medicine. Pandits traced the source of this paradox in the quality of medical education. It was propounded that medical education was lopsided; the curative-biased western model failed to properly equip the doctor to tackle the health problems of the Indian people. It was because of this western model, doctors settle in urban areas, itch to migrate to western countries, and practice individual medicine. It was, therefore, proposed that community medicine should be taught and emphasised more and more in the curriculum. New syllabi were introduced accordingly. The department of preventive and social medicine was created and upgraded; the internship period was extended from six months to one year, the R.O.M.E. programme was introduced to give field training to medical students. But the broad community of teachers, who were expected to turn this new revised programme into reality, were not taken into confidence during this entire exercise. In fact, community medicine eventully came to be another subject to be taught by the department of PSM and was required to be learned by the students for examination purposes. Thus community medicine remained a paper exercise; it was not even practised anywhere to serve as a demonstrative model for the students. Neither educational administrators nor teachers had any field knowledge or experience about what community medicine aimed at.

Teaching method underwent little change except adopting themselves to the changing content of the syllabus and changing structure of examination. An integrated teaching approach, by which the student could have a holistic view of the world of medicine as well as the aim of community medicine and which would have enabled him to appreciate the importance of studying different subjects in the pre-clinical and clinical courses to prepare him to be a doctor, was not taken into consideration. Even the modest WHO sponsored programme of integrated teaching in Maternity & Child Health where teachers from the discipline of Paediatrics, Obst. & Gynaec. and P.S.M. join together in a limited way, to explain to the students the disease process in the social context and the methods of tackling it, remained limited to only three centres in India. There also it is being followed perfunctorily. The object of teaching had been and still remains to be an exercise to prepare the student for the examination.

Control of Medical Education

There are three agencies for control. Medical Council of India (MCI) determines the overall standard. MCI prescribes minimum qualification of eligibility of students and teachers, necessary material requirements of a medical college eg space, laboratory, teaching aids etc, sets up teacher-student ratio, student-bed ratio etc and authorises curriculum. Affiliating University sets up detailed curriculum within the framework authorised by MCI, conducts examination and confers degrees and diplomas. Government, who runs the colleges, admits students, appoints teachers and provides the material infrastructure for teaching, including the hospital.

Over the years, control by the MCI and the University has been reduced to a notional character and the Governmental control, which is exercised largely by bureaucrats who are neither doctors nor teachers, has steadily tightened its grip. This control is exercised through financial allocation and through appointment-transfer-promotion of teachers. The teacher actually enjoys a large amount of freedom of manoeuvre in his/her own area of activity ie actual teaching and examination where external supervision and control is minimal, often non-existent. But the teacher has to bow to the bureaucratic fiat whenever called upon to do so.

A sinister trend is being noticed in the medical field in West Bengal since 1983. The ruling party, in its zeal to enlarge its sphere of influence, is (mis)using administrative machinery in order to exercise its control over every level of medical education. The Left Front government has constituted different committees for selection of teachers, for elevation of their academic rank at every level and their transfer. These committees are being manned by pliant people who owe allegiance to the ruling party. Those who are not ready to be used as plectrum are being deprived of their dues. Further, the ruling party, by virtue of its control over the university administration, has played havoc in admission to under-graduate and post-graduate courses, through manipulation over examination results—even prior disclosure of questions has been alleged on several occasions in the mass media. The most scandalous practice which has made headlines is the system of admitting in the MBBS course, wards of ministers, MLA, police officers, businessmen etc, who have been unsuccessful in the admission test, through special power of the chief minister. This indirect political control is undermining academic independence as a whole and bodes ill for the future.

Status of Medical Teachers

The status of medical teachers in the world of medical education is determined by a number of factors, eg (a) The speciality or subject; (b) The status of the teacher in medical practice; (c) The status of the teacher in profession/service.

The subject taught has a lot to do with the status of a teacher. Clinical subjects eg medicine, surgery, obstetrics and gynaecology, eye, ENT etc where diagnosis and management of diseases are dealt with, are accorded extraordinary importance for the reason that these subjects deal with the living beings—patients who need succour. The non-clinical subjects eg anatomy, physiology, pharma-

cology, biochemistry etc, do not deal with patients and hence are treated as unavoidable nuisances. Para-clinical subjects eg pathology and radiology, though do not make direct interventions in treatment, have nevertheless to come in contact with patients and hence, are given some importance. PSM comes nowhere amongst these divisions and hence, ignored like the non-clinical ones. In the practice of medical care also, doctors (and teachers) belonging to clinical disciplines are looked upon by the entire society as the real persons of importance. Policy-makers, planners and administrators are concerned with clinical subjects only. Progressive commentators on health leave out non-clinical and para-clinical subjects from their deliberations, people at large do not even recognise the teachers dealing with these disciplines as doctors. Students search for ideals among the clinical teachers. In West Bengal, only teachers of clinical discipline and radiology are allowed the privilege of private practice so that these all-important persons do not suffer from financial deprivation. These privileged teachers thus can live as members of the upper economic class of the society and pose as role models for the students.

A look at the remuneration enjoyed by the medical teachers is relevant here. On the salary scale, medical teachers are situated below the level enjoyed by general college and university teachers. General teachers have been enjoying UGC pay scale since 1973, whereas medical teachers in West Bengal were given the benefit of UGC scale only in 1981. General teachers now enjoy a much higher pay-scale as recommended by the Mehrotra commission while medical teachers are still lagging behind in the old UGC scale. In the report of the second Pay Commission (1977-80) of the government of West Bengal, the member-secretary observed

> It is doubtful whether conditions of service of the teaching posts on the UGC pay-scale are exactly the same as those teaching posts in West Bengal Health Service. The teachers in the other academic institutions who are in receipt of UGC pay-scale have a limited number of instructional periods in a week. They enjoy vacation and holidays which are not similarly available to the teaching posts in the medical line. This difference apart, the holders of teaching posts in West Bengal Health Service have to do hospital duties which are onerous in nature. The tremendous pressure of population on hospital services has made their duties all the more onerous. There exists a good case for distinguishing the teachers in the medical institutions from their counterpart in the other academic institutions.

The points for distinction are as in the table:

	Average age of eligibility for lecturership.	UGC pay scale granted in	Duty period	Job requirement.	Age of superannuation.	Pay-scale
College Teachers	25 Years	1973	18 hrs/ week.	Teaching	60 yrs.	Rs.2200 -5700
Medical Teachers	38 Years	1981	30 hrs/ week & 24 hrs a day on-call.	Teaching & whole-time medical service in the hospital.	58 yrs.	Rs. 700 -2500

In West Bengal, the clinical teachers have been given the option of private practice in lieu of a 30 percent cut in their salary; in addition—they are debarred from the highest pay-scale (ie their pay-scale is limited to Rs. 700—1900). Consequently, the amount of gratuity and pension also is small. The clinical teacher, therefore, is asked to perform the whole-time job of teaching, whole-time job of a clinician in the hospital and then a whole-time engagement in private practice— a task obviously impossible for a human being. The teacher, in reality, is confronted with a choice to prefer one whole-time job among these three and he, like the average citizen, opts for the profitable one ie private practice. It is a somewhat universal picture that the clinical teachers are accustomed to look upon their salary as a sort of fringe benefit and concentrate on private practice with a fierce dedication to earn as much as they can while the opportunity exists. No wonder, when the state governments in Bihar, Orissa, Andhra Pradesh, Assam etc, withdrew the privilege of private practice, clinical teachers fought at every stage to retain it. In West Bengal, private practice for medical teachers was prohibited in 1982. A case was instituted at the high court and the order was stayed. Soon after, the health portfolio which was under RSP—a constituent of the Left Front, was taken away by the major partner of the Front—CPI(M). The new health minister showed reluctance in implementing the order and the merry atmosphere of private practice continues. Needless to mention, private practice not only offers a return of several times more than the salary figure but also demands a sincere and engaging attention from the clinician. It is simply not possible for a clinician successful in private practice to do justice to the job of teaching and hospital tasks. He has to make a choice, set up a priority.

Then again, among the medical teachers, non-clinical teachers, deprived of status and respect and envious onlooker of their clinical colleagues, fortunes are a frustrated lot who have lost interest both in teaching and in their subject. A good number of them find solace in unauthor-

ised clandestine private practice while others lament. West Bengal has two post-graduate medical colleges where all teachers are forbidden private practice. Their conduct follows the line of the under-graduate non-clinical teachers, ie either clandestine private practice or disinterest in job.

This system of private practice to compensate the clinical teachers has given rise to the following problems:

i) Practising teachers are inclined to settle in Calcutta where the market for private practice is lucrative and are reluctant to accept transfer to another medical college, particularly a distant rural one as it would disrupt the practising network which they have diligently built up with years of effort. The rural medical colleges (there are three in West Bengal) therefore, suffer from a perpetual shortage of teachers.

ii) There is always a long waiting list of doctors possessing eligibility for a teaching post in clinical disciplines and under the unavoidable influence of the law of demand and supply, this situation has resulted in rampant corruption in the matter of teaching appointments. The competition for a teaching post in clinical disciplines has further intensified due to preference for a Calcutta posting. Consequently, clinical teachers try their utmost to retain their Calcutta-posts and resort to questionable means including inciting students to launch agitation demanding the retention of their favourite teachers.

iii) Non-clinical disciplines perpetually suffer from dearth of teachers, not to speak of competent teachers. Aspiring teachers vie for a teaching post in the clinical discipline and barring a few, opt for the non-clinical discipline only when they fail in their endeavour. They accept such postings reluctantly and then try somehow to live with it.

iv) Appointments in the post-graduate colleges are likewise resisted as these are compulsorily non-practising. Teachers in these institutions being non-practising not only suffer financially but also are placed on a lower level of social recognition than the practising ones. Thus they become frustrated and reluctant. Standard of post-graduate medical education has, therefore, deteriorated considerably. In the absence of any incentive, research work, required to be conducted by students, have been turned into paper exercises only. Practical training for students is lopsided. Even among the post-graduate students there is keen competition for the clinical disciplines resulting in corrupt practices in admission and examination, while non-clinical disciplines suffer from dearth of applicants.

What is To Be Done?

The standard of teaching has steadily deteriorated over the years. Zealous attempts to politicise health service has undermined the morale of the doctors including teachers. Non-clinical teachers have little interest in teaching. Teachers of clinical disciplines look upon such appointments as a means of personal aggrandisement and of earning money. Students are merely after the degrees which they would use as capital for their business in medical practice. They have learned the bitter truth that connections in places of influence will fetch them their desired objective—an under-graduate or post-graduate degree/diploma. In such a context, attempts to devise a meaningful methodology of teaching or to revise the curriculum have little relevance. Whatever might be the objective of such an exercise it should not be forgotten that it is the teachers, after all, who are expected to implement the programmes. If objective conditions are not set up so that the teachers participate actively, no programme will succeed.

Another aspect of this messy situation is worth pointing out. The degradation of standards of education makes its own impact on standards of medical practice. Commercialisation apart, scientific excellence in medical care is conspicuous by its absence. Bereft of a rational approach, medicine is being practised as a shot in the dark. Unscientific drugs are being used at random. Modern safer and more effective investigative and operative technologies have not reached even the upper strata of medical practitioners. The less said about clinical research the better. In fact, in the absence of a continuous updating of knowledge, a sort of quackery is rampant even among practitioners holding post-graduate qualifications, not to speak of general practitioners.

Frankly speaking, in the practice of modern medical science, science is the real victim in India. Low levels of scientific knowledge among the medical profession, particularly teachers, have rendered them easy prey to the profiteering campaign of drug and equipment industry. Medical literature, produced mostly by teachers, has not made any positive significant contribution to the development of medical science in the country. An unsavoury example may be cited to give an idea about the hollowness of the medical establishment. Two years ago at the national conference of the orthopaedic surgeons, a paper was presented as a critique of a number of original research articles published during last several years in the orthopaedic journal. Analysing the crucial contents of the articles and citing evidence, this paper revealed that all articles were the products of plagiarism without acknoledgement from the articles published in foreign journals. Scrutiny may show that the picture is no different in other specialities.

Independence or autonomy of teachers, updating of standards and 'check and balance' in career prospect are the areas needing consideration and overhauling. Independence starts with the removal of financial dependence on private practice. The last two Central Pay Commissions

Medical Education in India: Who Pays?

ravi duggal

It is with the aid of public resources that medical education and the subsequent production of medical humanpower has consolidated itself. Most of this humanpower finds its way into the private sector. Even worse there has been a sustained migration of doctors mostly to developed countries. This we feel is a serious concern. Public resources must be used for public benefit.

MEDICAL education in India is almost entirely the responsibility of the state. Ironically between 2/3rds and 3/4ths of those qualifying from public financed medical schools participate in the private sector. This means for every three allopathic doctors the government trains at the cost to the public exchequer for its own health services, it also trains seven doctors for the private sector at public cost. Besides this a more or less similar pattern exists for non-allopathic medical education (Ayurveda, Unani, Siddha and Homoeopathy) which together accounts for twice the number of allopathic doctors. As though this drain on the public exchequer is not enough, out of every 100 allopathic doctors going to the private sector between 34 and 57 have been migrating out of the country each year, mostly to developed capitalist ones, and recently also to the Gulf countries. This is indeed gross injustice to the poor Indian masses who have contributed their mite in training these doctors in the hope that they will in turn care for them. However, the focus here is not the dynamics of this injustice, which is so openly and unashamedly practised, but to view in a historical perspective the growth and financing of medical education in India.

Prior to the First Five Year Plan there were 28 medical colleges (unless otherwise specified we mean allopathic), all except one being publicly owned, from which about 2500 doctors graduated every year. By the end of the Second Five Year Plan the number of medical colleges had doubled and the doctor outturn increased 2 $^1/_2$ times, and at the start of the Fourth Five Year Plan the number of medical colleges had quadrupled and doctor outturn increased six times (see table 1 and 2). Most of this growth was in the state sector and with the aid of public resources. After the Fourth Five Year Plan the increase in medical education facilities have been very small but expenditure has increased at a galloping pace.

As of present (1987) there are 123 medical colleges in the country with 102 being owned and run by the government or other public bodies like the municipal corporations (four colleges) and universities (three colleges). The remaining 21 colleges are owned and run by private bodies, with most of them getting some financial assistance or subsidies or support from the state in conducting the colleges. Thus, it is largely with the aid of public resources that medical education and the subsequent production of medical human-power has consolidated itself.

This drain of public resources, especially of doctors is only one dimension of the expropriation of medical education, the other is the concentration of the outturns from medical colleges in the urban areas (see table 3), even in the state health sector which can be seen. Between 1952 and 1983 the number of hospital beds had increased 3 1/2 times but as a ratio to the population it had increased barely twice. Thus in the first plan period there was one hospital bed for 2717 population but in 1983 the availability of beds had increased to one bed for 1362 population. But, this aggregate picture is misleading because of the concentration of available facilities in urban areas.

Thus between the first and sixth plan periods the availability of hospital beds changed from one per 706 population to one per 395 in the urban areas in comparison to rural areas where the change was from 9438 population per bed to 5937 population. Since the distribution of medical humanpower data is not available in a disaggregated form the distribution of hospital beds may be assumed as an indirect indicator. Thus in the first plan period only 39 percent of hospitals and 23 percent of beds were in rural areas when 80 percent of the population lived there. In contrast in 1983 when about 76 percent of the population was in rural areas the availability of medical care facilities in comparison to urban areas had declined to 26 percent of hospitals and 17 percent of beds in rural areas. In 1987 the number of hospital beds in rural areas declined further (from 1894 in 1983 to 1633 in 1987) accounting for only 21 percent of all hospitals, the proportion of beds stayed at around 17 percent. In the case of government hospitals the situation is equally bad— in 1983 of all government hospitals a quarter were in rural areas and of all hospital beds in the state sector only 10 percent were in rural areas (CBHI/GOI, 1985). While there is no direct data of medical humanpower available, except 1981 census data — according to the 1981 census of all working (main earners) allopathic doctors only 28 percent worked in rural areas and of all nurses and midwives 38 percent were in rural areas (Census/GOI, 1987).

Besides allopathic services and humanpower there are non-allopathic institutions and humanpower— ayurveda, unani, siddha and homoeopathy. In terms of health care facilities (hospital and dispensaries) in these systems of medicine, the ratio to allopathic facilities is fairly small but humanpower of these systems of medicine is far larger than that of the allopathic (see Tables 3 and 4). Also, in comparison to allopathic doctors, a much larger proportion of non-allopathic doctors are found in rural areas —56 percent according to the 1981 census. Thus in the year

1986-87 there were totally 830, 400 doctors of all systems of medicine, besides 210,000 nurses and over 10,000 dentists (see Table 4). In addition to this in the same year there were 372,140 paramedics (ANMs, MPWs, Midwives and LHVs) (CBHI/GOI, 1988). If we take doctors of all the systems and calculate the ratio of doctors to population we find that in India one doctor exists for every 935 persons, and assuming the rural/urban distribution of the 1981 census we estimate that in 1986-87 for rural areas there is one doctor per 1574 persons (for allopathic one per 6116 persons) and for urban areas there is one doctor per 421 persons (for allopathic one per 793 persons).

Thus it is amply clear that humanpower resources in the health sector as regards the number of doctors is quite adequate, establishing the fact that medical education in terms of supply of doctors has kept pace with the growth of population and is today at a level (or supply) that is sufficient to meet the needs of the country's population. However, the hitch is that it does not meet the needs of the people because a large majority of doctors take up private practice, concentrate in urban areas or migrate abroad — in fact, more allopathic doctors migrate abroad than go to rural areas of India.

As stated earlier, medical education in India has been almost wholly financed by the public exchequer. This money comes mostly from tax revenue collected by the government from the people. Direct payment by students in the form of fees etc is presently very small.

Before we look at the data on medical education expenditure it will be in order to explain in some detail the structure of the state health sector financing.

State health expenditure is divided into three major heads called 'medical', 'public health' and 'family welfare'. 'Medical' is further divided into 'allopathy' and 'other systems of medicine' (non-allopathic). The main sub-heads under allopathy are (a) direction and administration (b) medical relief (c) education, training and research (d) ESIS and CGHS (e) and other sub-heads, and under 'other systems' there are separate sub-heads for ayurveda, unani, siddha and homoeopathy. 'Public Health' is divided into 'Public health and sanitation' and 'sewerage and water supply'— the former being mainly expenditure on communicable diseases prevention programmes and the latter mainly rural and urban water supply schemes. The 'Family Welfare' account includes expenditure on rural and urban family planning services and maternity and child health services.

All the three accounts have a 'capital outlay' section which is mostly construction activity. Thus, under 'medical' the main sub-heads are construction, expansion and improvement of (a) hospitals, dispensaries and health centres and (b) medical colleges. Under 'public health' it includes almost entirely water supply schemes and under 'family welfare' construction of family planning centres.

In this article we are concerned with the sub-head 'medical education' under the medical account section. The data on state expenditure on medical education being analysed here is for the period 1951-52 to 1982-83, a total of 32 years, from the First Five Year Plan to the middle of the Sixth Five Year Plan. The expenditure reported here is 'revenue expenditure'— that is, expenditure incurred out of revenues collected by the state and covers the union government and all state and union territory governments. This expenditure includes only the component spent on medical, dental and nursing colleges. The hospital and other supportive services needed for medical and nursing education are not included in this amount—this component of expenditure is not available separately. Capital expenditure is excluded from 'medical education expenditure'. We will deal with this separately.

Between 1951-52 and 1982-83 the state's expenditure on medical education has been substantial. It has seen a healthy growth of 2.8 percent per year in sharp contrast to 1.4 percent growth rate of total state health expenditure and only 1.24 percent growth of total government expenditure (CAG/GOI, various years).

At this stage we would like to emphasise that it is not possible to calculate how much is spent on training of each medical person because detailed breakups of expenditure on each category of personnel are not available and the supportive, administrative and hospital costs incurred for training are also not known. Performance budgets of states may provide this information but for macro analysis this information is too voluminous to put together because it is available for each college separately. Even here,

however, the supportive costs cannot be known—only field studies at the teaching hospital level will help in breaking down these costs. For instance, in Maharashtra, of the total expenditure on medical education for the years 1981 to 1989 on an average 84 percent was spent on training of MBBS doctors and the rest on other personnel (see Table 6). If we assume this proportion for India for the year 1983 then the cost per doctor to the state for only the medical college component works out to Rs. 84951.78. In the same year, given the average cost of Rs. 50 million per medical college and teaching hospital (on the basis of data for Maharashtra) the annual cost per qualifying student for the teaching hospital (excluding medical college expenditure indicated above) works out to Rs. 372,312.35. Let us also assume that this entire cost is necessary for training of medical humanpower. Taking the same proportion of 84 percent as expenditure for MBBS doctor training Rs. 312,742.37 becomes the teaching hospital cost per doctor and the total cost per doctor totalling to Rs. 397,694.15 (Please note that we are taking one year's expenditure on medical education and teaching hospitals to be the cost of the $4^{1}/_{2}$ years. This method is perfectly okay because in any one year there are 5 batches of medical students. Thus if we divide the above figure by five we will get per medical student cost per year and if we again multiply by $4\ ^{1}/_{2}$ -we prefer 5 — we come back to the same figure). Whether this approach is correct is debatable but the fact that a supportive structure of a teaching hospital is needed for medical education cannot be discounted. Whether the present type of teaching hospital is the right type is a different question altogether but the inclusion of the entire cost of teaching hospitals as part of medical education, we feel, is perfectly justified — and this cost today (1988) in Maharashtra is Rs. 80 million per teaching hospital (for JJ Hospital and Grant Medical College, Bombay the cost is Rs. 150 million). Besides, administrative and capital costs have not been included.

In the First Plan period the state spent Rs. 66.4 million on medical education. (See Table 5) During this period 12,520 MBBS doctors, 657 postgraduates, 142 dentists and 9345 nurses and general nurses qualified from the 41 medical colleges, 7 dental colleges and 241 nursing schools/centres. (Table 1 and 2). This expenditure working out to Rs. 13.28 million per year, was 5.3 percent of all expenditure on medical services by the state and 3.5 percent of the expenditure on total health care (including FP, public health and water supply) spent by the state. (Table 5). More than one - half of this expenditure was by the union government and the three provinces of Bombay, (Gujarat and Maharashtra) West Bengal and Madras (Tamil Nadu). This concentration of expenditure in these provinces continues even today. (See Table 7).

Source : *Health Information of India* (earlier called *Health Statistics of India* and *Pocket Book of Health Statistics*). CBHI, GOI, various years.

In the Second Plan period, expenditure on medical education almost tripled in contrast to less than doubling of health expenditure. The average annual expenditure on medical education during this period had increased to Rs. 38.04 million which was 8.3 percent of state health expenditure. (Table 5) This is reflected in the 46 percent increase in the number of medical colleges, a 28 percent increase in outturn of MBBS doctors and over 2 $^1/_2$ times increase in post-graduates.

Between the Second and Third Plan periods state medical expenditure leaped again by 2 $^1/_2$ times averaging Rs. 93.3 million per year during the Third Plan period. The number of medical colleges had more than doubled now in comparison to the First Plan Period, and the outturn too had leaped to 24631 from 16047 in the Second Plan — a 53 percent increase. The post-graduate outturn again increased at a much faster rate of 134 percent between the Second and Third Plans. Medical education expenditure in the Third Plan period, increased to 12 percent of medical services expenditure and 7 percent of health care expenditure. (Table 5).

The pattern of growth continued through the Plan Holiday and Fourth Plan period when state expenditure on medical education was 14.3 percent and 16 percent respectively, of state medical services expenditure (Table 5). By the end of the Fourth Plan there were 105 medical colleges in India (96 owned by public bodies) and the outturn of medical graduates in the Fourth Plan period was 55,818 medical graduates and 8198 post graduates. By this time the production of dentists had picked up and every year about 468 dentists were qualifying. However, the growth in the production of nurses remained slack, as even in the Fourth Plan period only one nurse was being produced for every two MBBS doctors. (Table 2).

The situation in the Fifth and Sixth Plans did not change very drastically. Between the Fourth and Fifth period the production of post graduates almost doubled. The ratio of production of nurses to doctors worsened in the Fifth Plan, though improving slightly in the Sixth Plan (Table 2). The expenditure on medical education in these two Plans stabilized at about 13 percent of medical services expenditure and 7 percent of health care expenditure. The average annual expenditure on medical education in the Fifth and Sixth Plan was Rs. 60.8.94 million and Rs. 1187.43 million, respectively (Table 5). Today (1988) this expenditure is about Rs. 3000 million (estimated by author) and against this about 13,000 medical graduates, 4500 postgraduates, 700 dentists and 10,00 nurses are being produced. Besides this there is capital expenditure incurred every year. This data in the national accounts is available only from 1974. Thus in the 5th and 6th Plan periods if capital expenditure on medical education is added to the medical education expenditure, we see that capital expenditure accounts for 10.5 percent and 19 percent of this combined expenditure, respectively, increasing the 5th and 6th Plan annual expenditure to Rs. 680.1 million and Rs. 1467.07 million, respectively. (Table 5) This is a phenomenal expenditure when we consider the fact that between 80 percent to 85 percent of this goes to production of medical graduates and that 75 percent of these graduates go to the private sector. By any standard this is a phenomenal drain on the resources of the public exchequer.

As if this is not enough there is another aspect of this drain of resources. Since the First Plan period the migration of doctors to other countries, especially developed ones, has been very high. In the First Plan period 810 doctors were migrating every year. In 1986-87 this figure had reached 5304. (Table 8). At this figure in comparison the outturn of medical graduates than in the First Plan, 32.35 percent of doctors migrated abroad and in 1986-87 40.8 percent did so. This high rate of migration is very closely linked to imperialism. Our entire medical

education curriculum is western oriented. Doctors are trained in a system which best suits the system of developed capitalist countries. This encourages migration. Not only this but international funding and via it policy too plays its role in causing the continuation of the existing system. For instance all the schools of medical excellence (AIIMS, PGIMR etc.) have been set up with assistance of imperialist agencies. As an example, between 1950 and 1974, nearly 99 percent of all health sector assistance by the Rockefeller Foundation to India went to medical education and research, including attractive fellowships for study abroad (Rockefeller Foundation, various years). Thus, not only do doctors go to the private sector but a significantly large number migrate to other countries as well.

This, we, feel is a serious concern. We are not against the investment of medical education; in fact, if necessary, investment must be increased. What is wrong is the drain of public resources for the benefit of the private sector and of imperialism (through migration). To conclude we feel that the outturn of medical education needs to be regulated. Public resources must be used for public benefit only— this should be the principle in regulation. The mix of expenditure also needs to be changed. More resources have to be committed to the production of nursing professionals whose numbers are only one-fourth of what should exist in India today. Thus a drastic change is needed in the investment and expenditure policy for medical education in India to change radically the growth patterns of medical education and expenditure on it. This change is even more urgent presently, given the wave of privatisation. In 1988, for instance, 13 new medical colleges have been sanctioned, bringing the total to 146 medical colleges; and the striking feature of this is that 12 of these colleges were in the private sector. The danger here is that even private colleges are funded through public finances. Like education in general, this is also true of medical education.

REPRODUCTIVE AND GENETIC ENGINEERING

[Journal of International Feminist Analysis] (published three times in a year) RGE is designed to facilitate the development of feminist multi-disciplinary and international analysis on the new reproductive technologies and genetic engineering and their impact on women worldwide. The policy of the journal is to recognise the use and abuse of women as central to the development of reproductive technologies and genetic engineering and to highlight the relevance of the application to these technologies to the past, present and emerging social and political conditions of women.

RGE is edited by International Editorial Collective and Editorial Advisory Board.

Political Economy of International Migration
Indian Physicians to United States

t k ishi

The number of immigrants from India, as well as other Asian countries, to the United States has drastically increased since the passage of the Immigration and Nationality Act of 1964, which overturned a previous restriction on immigration from Asia. Of the limited amount of literature written on the influx of Indian, most have focussed on domestic concerns: how new immigrants have been assimilated or discriminated against in the new place (Saran and Eames 1980, Fisher 1980). There is, however, much evidence to suggest that an international perspective is needed to fully understand this recent movement of Indians to the United States.

The purposes of this paper are 1) to present a theoretical framework to explain this phenomenon within the context of the international political economy, and 2) to apply this framework to the migration of Indian physicians to the United States for the period between the mid-60s to the mid-70s. This study is part of a larger project by the researcher on a comparative study on the international migration of physicians and nurses from Asia, mainly from India, Korea (republic) and the Philippines.[1] (This article has been reprinted from South Asia Bulletin, Vol II, No 1, 1982.)

BEFORE presenting the theoretical framework, previous theories on international migration should be briefly mentioned.[2] The first major theory deals with 'push' and 'pull' factors operating separately at the countries of origin and destination of migration. The weakness of this theory lies in its failure to see the complex relationship between the two sides of migration. Moreover, the theory tends to focus on individual motivations to migrate. The second theory is the 'equilibrium' theory from a neoclassical economic model. This explains international migration as a natural process of the movement of people to reduce existing inequalities in the supply and demand of labour, as well as in the incomes between the countries of origin and destination. However, this approach cannot explain non-economic variables such as immigration laws. Furthermore, this ignores the fact that international migration, on many occasions, resulted in unequal development, as in the case of migration to western Europe (Paine 1974).

Literature is increasingly available on international migration from a new perspective (Bach 1978, Bonacich and Hirata 1980; Castells 1975; Petras 1981; Burawoy 1976; Portes 1978). This perspective tries to see the international migration of labour within the context of 'core-peripheral' relationship. In other words, immigration serves as a deliberate tool to further the economic development of developed countries (DCs), while emigration is caused by the distorted development of less developed countries (LDCs), influenced by the dominance of DCs over LDCs.

The following study is based on the above approach and tries to examine the validity of the approach by applying it to a case study on the migration of physicians from India to the United States.

The basic variables for the proposed theoretical framework are as follows:

1) The labour need for the economic development of DCs;
2) The role of the labour sector in DCs;
3) The role of the governments of DCs;
4) The labour surplus caused by the failure of LDCs in economic development;
5) The role of the governments of LDCs;
6) The role of the labour sector in LDCs;
7) The cultural, economic and technological hegemony of DCs over LDCs.

DCs with successful economic growth up until the early 70s required a larger labour force in construction, services and professional fields. Also, a 'dual labour market' (Piore 1979), which produced a division in the primary and secondary sectors of industries, as well as in occupations, existed. Foreign labour filled the absolute shortage of labour, and the shortage created by the dual labour market as well.

The labour sector in DCs was very sensitive to immigration, particularly when domestic economies were declining. Fears of competition with foreign labour and lowering effects on salaries by foreign labour were aroused. This pressure from the labour sector in relation to the labour needs for economic growth was the concern of DC governments. As a result, from time to time, DC governments accommodated the above counter pressures, and manipulated the import of foreign labour with various legislations and regulations.

In response to the labour needs of DCs, LDCs filled these needs with their labour surpluses. In fact, the emphasis on gross national products for development plans in LDCs, by and large, neglected unemployment problems. Second, the neglect on the economic development of rural areas caused severe problems in urbanisation. Furthermore, the emphasis on the expansion of capital-intensive industries with the assistance of foreign capital and technology resulted in a retreat in the development of indigenous industries. As such, emigration pressure from various segments of the dislocated population rose

The governments of LDCs either ignored or encouraged the emigration of their own people. Indeed, emigration

served as a safety-valve for the acute unemployment situation in LDCs. Furthermore, remittances sent by emigrants from abroad became indispensable for LDCs to acquire the foreign exchange needed for their development strategies and debts in foreign loans. Generally speaking, however, the labour sector as a collective in LDCs was weak in influencing government policies. Therefore, the labour sector had nearly no influence on emigration itself. Nevertheless, in the administrative and professional sectors (including the medical profession) entrenched personnel successfully maintained their positions by excluding new entrants. In the general context of slow development, these frustrations faced by recent graduates forced many of them to emigrate.

Aside from the above framework, an understanding of the cultural, economic and technological hegemonies of DCs over LDCs which had a tremendous impact on migration from LDCs to DCs should be incorporated. Through these hegemonies, the flow of capital, technology, information and goods from DCs to LDCs apparently contributed to the emigration of people from LDCs to DCs.

The following piece of information is significant in order to grasp the above concept. The US Government recently began to concern itself with international migration in terms of its foreign policy, because most countries with high emigrant populations were major recipients of US foreign assistance, major partners of US trade and targetted areas of US direct investment [US Agency for International Development 1980; Morrison 1980]. Moreover, most countries of emigration were of the more developed countries among LDCs. This fact may suggest that the process of economic development in those countries was much related to the emigration of their own people despite, or because of, their intimate relationship with the United States.

Before concluding this section, two points should be mentioned. First, freedom to leave countries was granted, freedom to enter other countries was not. In this respect, the economic advantage of DCs over that of LDCs greatly influenced the direction of international migration.

Second, the relationship between DCs and LDCs was mutually interdependent, although not under equal terms. DCs had an overwhelming amount of power over LDCs through the movement of various factors such as capital, technology, military and information. Through this, the world economy became more and more systematically integrated into a global unit. In this respect, international migration cannot be comprehended if considered in isolation from the above perspective.

International migration was sought after in DCs as a cheap and substitutable labour source to alleviate the labour shortage. At the same time, multinational corporations left DCs in search of a cheaper labour force in the LDCs. Thus, the concept of an international division of labour is crucial for understanding contemporary immigration in the context of the political economy of DCs and LDCs.

The following is a case study of the migration of Indian physicians to the United States from the mid-60s to the mid-70s. This case could be considered as part of the 'brain drain'. Although the theoretical framework discussed earlier does not specify the migration of high level manpower, such migration can be similarly regarded as a phenomenon of international labour migration due to the role it has played [Portes 1978]. Thus, the framework discussed will be used to analyse the following case study. The reason why physicians are of particular interest is that more data and literature is available for this group than for other occupational groups, and second, that the number of physicians who came to the United States is remarkable.

The period from the mid-60s to the mid-70s was particularly chosen for study because it was during this time that, in a historical context, the international migration of physicians was most prominent. This means that beginning in the early 60s this migration phenomenon became acute and declined after the mid-70s. This case study, thus, focuses around this period; however, on certain occasions, as needed, the period prior to and after the mid-60s to mid-70s will be touched upon.

Magnitude of Immigration From India

In viewing the immigration of Indian physicians to the United States, it should be understood that this phenomenon is only part of the general trend of the emigration of Asian Indians to other parts of the world during the 60s and 70s. One major trend was the immigration to DCs, mainly the United States, the United Kingdom and Canada.[3] Another trend which became important recently was the immigration to the oil-producing Middle East [McCarthy 1979]. With this in mind, the magnitude of the migration of Asian Indians, particularly of physicians, will be described later.

As Table 1 shows, the number of Indian immigrants to the United States has been considerable since the passage of the Immigration Act of 1965. Prior to 1965, the immigration of Asians in general was severely restricted under the McCarran-Walter Act of 1952. Among various occupational categories, professionals and technical workers were the largest. This was, of course, due to the preference for professional immigrants in the immigration law. As a matter of fact, Table 1 shows that a significant number of Indian immigrants was admitted under the third preference of the immigration law, which includes professionals, scientists and artists, although, since the mid-70s, more non-professionals are tending to immigrate. (See Table 1)

In addition to the immigration statistics, the number of

exchange visitors and students was significant. The reason for this was that physicians who were exchange visitors were, first, potential immigrants, and second, performing duties and work in similar areas as were immigrant physicians. As for students, they were important because many stayed in the United States to seek employment opportunities after completing their studies.[4] Table 2 indeed, indicates the magnitude of the numbers of Indian exchange visitors and students, as well as those who adjusted their statuses to immigrants while remaining in the United States. (See Table 2)

However, as both Tables 1 and 2 clearly show, a declining trend existed in the immigration of professionals and of those adjusting from non-immigrant statuses to permanent residents. This was mainly due to the further influx of relatives of US citizens and immigrants, and partly due to a restriction on the admittance of professional immigrants, particularly physicians, as will be discussed later.

Regarding the Foreign Medical Graduates (FMGs) receiving US licenses for the first time, their proportions to the total number of those receiving licenses rose from 5.1 percent in 1950 to 22.4 percent in 1968 [Kabra 1976:600].

In terms of Indian physicians, unfortunately, no chronological data, except for some fragmented data, is available. For example, a survey of Indians in the New York Metropolitan Area in 1978-79 showed that 16 percent were doctors [Leonhard-Spark and Saran 1980: 154]. New York State was the state which the largest number of new Indian immigrant, 24.1 percent between 1970-76, declared as their destination upon arrival [US Immigration and Naturalitation Service: 1970-76]. This fact implies the existence of a significant number of Indians immigrant physicians in the United States. Also, Table 3, although of a recent period, shows the magnitude of these numbers. This data, particularly in 1972, illustrates the existence of a significant proportion of Indian physicians to the total number of immigrant and exchange visitor physicians in the United States. (See Table 3).

In short, although accurate data on the number of Indian physicians in the United States is not available, the magnitude of immigrants, as well as exchange visitors apparently increased greatly after 1965. A study in India by the Council of Scientific and Industrial Research also revealed in 1973 the significance of the outflow of Indian doctors, along with scientists and engineers [Kabra 1976:75].

US Need For Foreign Medical Graduates

In 1970, the percent distribution of professionals in the United States was 14.6, while those in 1950 and 1930 were 8.6 and 6.8 respectively [Chen 1980 : 144]. This change in occupational distribution was partly a consequence of the demands for human capital by modern industrial sectors to sustain a high level in economic growth, and of great financial support in research and development from the government [Thomas 1968: 40-43].

In relation to the medical field, as Table 4 illustrates, total expenditure per capita and percent of the gross national product for health and medical care were increasing. What were the factors influencing the increasing expenditures for health care in the United States? Sorkin [1977:2], in answering this, states that the growing expenditures were mostly attributed to the utilisation of health care services and to inflation, but little to population growth because it was proportionately low. [See Table 4].

The most significant reason for the greater utilisation of health care services was the introduction of the centralisation of the health care system in the United States since the second world war. In the public sector, the basic change occured in 1966 with the Social Security Amendments to implement Medicare and Medicaid. Thus, the public expenditures for health care and the rate of total expenditures drastically increased since then, as seen in Table 4 [Sorkin 1977: 2].

In the private sector, total expenditure rose sharply due to a big expansion in health insurance plans, which were sucessfully resisted by the American Medical Association (AMA) before the second world war (Kim 1981: 150)

Another aspect of the demand for physicians was due to a maldistribution of physicians in the health service system in the United States. This meant, for example, that native physicians tended to choose suburban areas as sites for their more profitable private practices. Therefore, it left 4,000 to 6,000 unfilled positions per year in the inner-city hospitals [Mick 1975: 15, 18 and 19].

However, despite the fact that a drastic increase in the demand for physicians existed in the United States, the AMA failed to respond positively. It maintained a restrictive attitude towards the expansion of medical schools, as well as towards the expansion of national health services [Hock 1970: 27]. The physician/population ratio actually declined from 1950 to 1960 as seen in Table 4. In fact, such a 'cartel-like guild' attitude was intended to keep the income of the physicians high [Adams and Dirlam 1968: 260]. As already evident, although the AMA is not a labour group, it played a similar role as the labour sector described in the theoretical framework of this study. In short, the AMA pressured for the maintainance of the prestige and high incomes of US physicians by attempting to retain a monopoly on the labour supply.

Thus, facing a severe shortage of physicians, the import of FMGs (Foreign Medical Graduates) was needed, particularly for intern and residency positions in hospitals. As a matter of fact, during the mid-70s, one third of all the medical graduates in the United States were FMGs, which included many Indians. The result was to divide the physician population of this country, ie the United States, into two classes: natives and FMGs [Mick 1975: 14 and 17].

Moreover, it was natural that the import of FMGs was desired because it was quicker and cheaper than producing native medical graduates [Reddy 1974: 376]. It should be added that FMGs were faced with problems in state licensure and underemployment. This meant that many FMGs failed the state licensure examinations which allowed them to practice their professions, and that many worked in lower-skilled jobs such as technicians and assistants.[5]

Considering the shortage of physicians caused by the expansion of health care services and the reluctance of the AMA to produce physicians according to the proportionate need in the United States, the US government passed various provisions so that foreign professionals, mainly Asians remaining in the United States, could become immigrants, even before 1965.[6] Otherwise, Asian professionals were unable to become immigrants under the McCarran-Walter Act of 1952, which barred the admission of large numbers of Asian immigrants. Consequently, in 1965, despite the reluctance on the part of public opinion to admit non-white immigrants, other pressures from the government and business communities succeeded in changing the McCarran-Walter Act in order to receive more professional immigrants. Interestingly, this change was paralleled with the expansion of higher educational systems in many Third World countries. According to the new immigration law which became fully effective in 1968, professionals were, categorized under the third preference [Public Law 89-236]. It is needless to say that the influx of FMGs, including Indians, into the United States partially relieved the shortage of physicians, particularly in hospitals in this country.

In addition to the major change in immigration laws, other legislation in regard to the migration of physicians should be mentioned. First, the screening test for FMGs in 1958 by the Educational Council for Foreign Medical Graduates (ECFMG) was established. The test was administered in various countries outside of the United States, and FMGs had to pass the tests in order to be employed in the United States. Second, the Mutual Educational and Cultural Exchange Act of 1961, which provided the exchange Visitor Program, was modified in 1970 in a manner so that the two year foreign resident requirement for exchange visitors before they were eligible to become immigrants, was eased. This amendment [Public Law 91-225] offered incentives to exchange visitors to adjust their statuses. In fact, the number of adjusted FMGs became the major group of new immigrant entries, as Table 1 suggests [Stevens, et al 1975: 440].

However, the trend surely changed after the United States tightened the entry of FMGs with the Health Professionals Educational Assistance Act of 1976, under the Congressional assumption that there was no longer a shortage of phyicians in the United States. This act applied to both FMG immigrants and exchange visitors. Behind this legislation, pressure existed from the various bodies of the American medical profession not to rely on foreign physicians. English language ability and the quality of performance in the delivery of health care were reasons given. Thus, the influx of FMGs to the United States were severely interrupted. Of course, this new legislation greatly affected various hospitals in need of FMGs [Stevens et al 1978: 273-275]. It should be added that due to several health legislations after 1963, the rate of increase in the number of US medical graduates switched from 0.8 percent for the 1956-66 period to 4.8 for the 1966-73 period [Sorkin 1977: 87-103]. Therefore, by the late 70s, it was expected that US medical graduates would absorb the shortage. Thus, it can be said that the role of FMGs was temporarily to fill the shortage created by the delay in a sufficient production of US medical graduates.

As already clear, in addition to the US need for FMGs, various legislation and regulations similar to a 'tariff policy' [Thomas 1968: 40] played a significant role in the supply and demand of physicians in the US market. The international migration of FMGs to the United States was manipulated by different interest groups such as hospitals and the AMA (a quasi-labour group), and the government, as well. The next question to be asked, then, is, "Why did many FMGs in the United States come from particular countries such as India?"

Indian Reply To US Need

In India as in the educational expansion of most LDCs, higher education, in particular, was considered very essential for economic development in the face of an increasing importance of human capital. In fact, the annual growth rate in college enrollments and the total expenditures in higher education were 10 to 13 percent in the 50s and 60s [Ilchman 1974: 121]. Any attempts to restrict admissions in higher education was avoided because they were unpopular and politically unwise [Tobias 1968: 39]. Moreover, in addition to the inability of the Indian government to control the output of graduates due to its decentralised system in higher education [Domrese 1970 : 226], several five-year development plans failed to absorb the graduates into the Indian domestic labour market, leaving severe unemployment [Puttaswamaiah 1977: 79-106]. In short, the lack of coordination between education and human power planning caused educated unemployment, which led to the emigration of many educated people from India.

With regard to physicians in India, the situation was the same, although not as severe as for scientists and engineers [Ghosh 1979: 281]. The expansion of medical education in India after the nation's independence was great, particularly during the Third Five-Year Plan between 1961 and 1966. According to Mathur [1971: 76, 77 and 93], the actual annual intake of medical students rose from 2,675 in 1951 to 11,106 in 1968, along with a tripling in the number of medical colleges. And, the estimated surplus of

doctors in the future supply and demand of doctors in India, utilising various methods to estimate projected numbers, were 13,000 in 1971, and 32,000 in 1976.[8] Nonetheless, as long as a shortage of physicians in terms of a physician/population ratio existed, the production rate of medical graduates was expected to be larger than the growth rate of the population in India according to Indian planners [Tobias 1968: 140]. How could this contradictory phenomenon be explained?

One explanation lies in the maldistribution of physicians in India. This meant that most physicians refused to work in rural areas or public services because of lower remunerations and the lack of facilities available in those areas. Physicians were concentrated in big cities and developed areas where higher income was expected. [Marthur 1971: 61]. In the economic sense, the purchasing power of medical services in rural areas could not meet the expectations of medical graduates in terms of the expected high incomes and the cost for training these physicians. In addition, the lack of logistical facilities in rural areas and public services created a reluctance among physicians with specialized training to work there. Therefore, a mere consideration of the physician/population ratio in India, as a whole, could not be a sufficient indicator in planning the output of physicians. As Gish [1975: 5-7] describes, the maltraining and malutilisation of physicians should also be regarded as being important in understanding this unequal distribution between city and countryside.

In short, a lack of coordination between the desire to expand the production of medical graduates and an inability on the part of the country to utilise these graduates, along with the maldistribution of physicians caused unemployment problems for physicians, mainly in the major cities of India. Nonetheless, the employment concern of Indian economic development was treated as a minor problem. The emigration of Indian physicians, therefore, could be seen at least, as an alternative to resolve the unemployment problem by individual physicians seeking prospective jobs in other countries.

In terms of the employment structure of professionals in India, particularly that of physicians, it is not clear how the government viewed the emigration of their professionals. However, it should be mentioned that, as Banerjea [1975: 192] notes, favouritism, nepotism and seniority in appointments and promotion affected the younger professionals. Through the use of favouritism and nepotism, only those having political and personal ties with the hiring selection committees and promotion personnel tended to be selected. Thus, the qualifications of those seeking appointments or promotions were of secondary concern. Of course, this type of practice was also common in other LDCs.

The professional structure inherited from a British model also limited the opportunity for juniors, or younger generations, in terms of positions, as well as income [Dandekar 1968: 217-219]. Thus, the conflict between seniors, or established generations, and juniors, was serious, and many young professionals could not better their opportunities in India. In effect, 'elite feudalism' [Khadria 1978: 103] maintained the status quo of established professionals and prevented the incorporation of increasing professionals. Such negative factors, of course, facilitated the emigration of professionals, including physicians.

Upon considering the factors influencing the emigration of professionals, what were the responses of the Indian government? The situation of a brain drain was repeatedly discussed by LDCs. Yet, there was no definite assessment in regard to whether the migration of high-level manpower was a loss to the countries which produced emigrants, and how the LDC governments could prevent their people from leaving their countries.

India was not an exceptional case. Although India tried to discourage the 'brain drain,' it was actually not among the most urgent issues needing to be resolved, as will be described later. There were more acute problems caused by underdevelopment. The government, overall, could not effectively control the exodus of its high-level manpower.

It was only in 1958 that the Indian government took concrete action in establishing the Scientists Pool for qualified Indians abroad. The objective of the pool was to provide temporary placement for persons returning from abroad with high qualifications, mainly in science, technology and medicine, until they could find permanent posts in India [Abraham 1968: 88-90]. However, the pool system proved to be ineffective in encouraging qualified persons abroad to return home because it did not coordinate its efforts with existing employment opportunities and conditions in India [Domrese 1970: 250; Abraham 1968: 105-6; Tobias 1968: 190]. Moreover, although the government tried to bring back high-level manpower from abroad, it did not intend to prevent them from leaving India.

Concerning the medical fields, the government did take some actions against the emigration of physicians. One such action was the government banning of tests given by the Educational Council for Foreign Medical Graduates (ECMFG), which screened FMGs for work in US hospitals as interns and residents. Indian physicians, however, were still able to take the tests in neighbouring countries. Another action required medical graduates from state medical colleges in India to serve the public health system in medical fields for a limited period [Abraham 1968: 110]. These measures were apparently based on the absolute shortage of physicians in India as earlier mentioned, resulting from the low physician/population ratio, and the maldistribution of physicians in the country.

Although not particular to the case of physicians, the role of the Indian government in the emigration of high-level manpower, including medical manpower, is discussed below. As previously stated, the government did not seri

ously concern itself with the emigration situation. For example, in a report by the Education Commission for 1964-66, a statement indicated that the 'brain drain' issue was over-exaggerated.[9] What were the underlying reasons behind the neglect on the part of the government concerning this very issue?

It appears that there were two major reasons for the neglect. One was that the government was unable to tackle the problem of unemployment, in general, and of its educated people in particular. This implied that the issue was 'overflow' not 'brain drain' [Baldwin 1970: 358]. Whether or not it is appropriate to use the term 'overflow,' it is definite that the emigration of high-level manpower, including physicians, served as a 'safety-valve' against the acute unemployment situation [Blaug 1969: 161]. It was also true that educated unemployment was a political threat to the state because the educated were influential enough to address their own concerns.

Another reason was related to the foreign exchange reserve. India, as one of the developing countries, received a large amount of foreign capital through foreign assistance and direct foreign investment in order to develop its economy. Nevertheless, in doing so, India became largely reliant on foreign capital historically from the United Kingdom and contemporarily from the United States. It is needless to say that foreign exchange was also required to pay off debts accumulated through foreign loans, and the import of oil, machinery and technology.

In relation to the emigration issue, the governments refusal to grant foreign exchange for the operation of the Association for Service to Indian Scholars and Technicians (ASSIST) in the United States and the United kingdom, which was to coordinate Indian high-level manpower from abroad and provide placement in India, implied a priority set on foreign exchange by the government [Tobias 1968: 192]. Such concerns were reflected in the control of foreign exchange acquired through the Reserve Bank of India. And in the case of medical graduates, they were able to receive foreign exchange conditionally [Domrose 1970: 246 and 247]. In short, as Blaug [1969: 159] states, the 'brain drain' was unfavourable, but the foreign exchange problem was worse.

Along with the decline in foreign exchange reserve, the importance of remittances sent by Indians abroad began to play a significant role in acquiring foreign exchange, as Table 5 illustrates.[10] Various measures taken by the government to encourage the emigration of Indians into the Middle East were such an example [Nadkarni 1978]. In respect to the emigration to the United States, the situation was not clear, but a large amount of remittances to India was, naturally, expected.[11] (See Table 5).

In sum, the overall policy of the government regarding the emigration of professionals consisted in posing few or no obstacles to their leaving the country. There is no doubt that, unlike the Soviet Union, the Indian government did not want to be scrutinised over the human rights of people to leave the country freely by heavily taxing the people [Bhagwati 1976: 13]. To the contrary, as in the case of the emigration to the Middle East, the government even encouraged the emigration of its own people whether they were labourers or professionals due to acute unemployment and the lack of foreign exchange in India.

US Indian Linkage

It has, thus far, been argued that the emigration of Indian physicians to the United States was caused mainly by US demand, and partly by a surplus of physicians in India resulting from the underdevelopment of the country. Also mentioned was that population movement as such was directly promoted by immigration legislation in the United States. However, in the final section of this paper, the linkage between the two perspectives, the United States and India, will be discussed. In fact, the US-Indian political economy is a basis for understanding the migration.

Beginning in 1956 through the Second and Third Five-Year Plans, the Indian government emphasised the expansion of the public sector by introducing heavy industries.[12] As a matter of fact, the development of industires in the production of goods, particularly steel, machinery and chemicals, was accelerated during this period. On the other hand, this tendency to place an intensive emphasis on the heavy industries of the public sector caused reactions in the Indian economy, as a whole. For example, by ignoring other sectors of the economy, eg agriculture and small enterprises, such problem as stagnant agricultural production and the existence of widespread manual industries were perpetuated. This situation led to an imbalance in trade because India had to import agricultural goods as well as machinery and equipment, and to maintain its investments throughout the Five-Year Plans. In addition, by neglecting light industries, where its strength was, India's exporting powers were weakened. Therefore, Table 6 illustrates the trade deficit expanded from the late 50s to the late 60s. However, the domestic market which was to absorb the output of newly built heavy industries remained weak. This was due to the continuing existence of the widespread poor segments of the Indian economy, which was perpetuated by the industrialisation policy. As a result of this gap between the primary and secondary sectors of the economy, India, lacking the capital to import goods and to maintain its industrialisation policy, began to rely on foreign capital, either in the form of aid or direct investments. (See Table 6).

In looking at Table 6, it is obvious that the proportion of Indian import from the United States increased from 13.1 per cent in 1955-56 to 38.0 per cent in 1965-66, and also that the United Kingdom underwent a decline in its influence.

Such a shift in influence from the United Kingdom to the United States was a clear manifestation of the US hegemony over India during this perod, as well as over other Asian countries. Table 7 illustrates the magnitude of US foreign aid throughout the world. To be sure, India was the largest recipient of US foreign aid throughout the mid-50s to the late 60s. Of course, this was due to the economic potential and strategic importance of India as noted by the US agency for International Development [1966: 106]. The US share in foreign aid to India was the largest, at 51 per cent, not mentioning the share from the World Bank, which was primarily US controlled [Ito 1972: 126]. (See Table 7).

While Indo-US economic relations were deepened through trade and aid, direct foreign investment in India also was outstanding beginning in this period. The US share increased 9 per cent in 1955 to 27 per cent in 1968, while that of the United Kingdom declined from 83 percent to 41 percent in 1955 and 1968 respectively [Ito 1972: 131]. This meant that India ceased to be a monopolised market for the United Kingdom, while the United States became more influential. In fact, as Table 8 shows, US investment in India, through US affiliations and rupee companies controlled by US capital, as well as technological collaborations, increased tremendously beginning in the 60s (See Table 8).

India did not take a policy of export expansion until the early 60s. Capital flowed mainly from the United States in the form of aid and private investment, which became indispensable for the increase and/or maintenance of the output of Indian industrialisation. A huge deficit in the balance of payments in India made it difficult to pay loans previously received. The situation was aggravated by the Indo-Pakistan War of 1965, along with the temporary stoppage of US aid. With this crisis in India, India changed its development policy after 1965 by devaluating the rupee, relieving economic control by moving towards liberalisation, implementing the 'green revolution' and emphasising the development of the private sector. Needless to say, this modification was to accommodate a strong outside pressure, primarily the World Bank, belonging to the Aid-India Consortium, led by the United States. In this respect, having already relied on foreign collaboration from the United States in particular, the Indian economy hence became deeply involved within the US hemisphere.

Important, particularly for understanding the migration of physicians, is the factor of the hegemony of US technology over that of India. As Kabra [1976: 53] explains, technological 'colonialism' became a common feature in India through the instrument of multinationals. Since multinationals utilized their own technology which was under continual change and was brought from abroad for commercial use, it was impossible for India to keep up and digest the imported technology. As a result, large-scale industry, with foreign collaboration, slowed down the development of the indigenous technology of India. Therefore, Indian telent became isolated and was not able to contribute to the country's own technological development [Ray 1971: 2061]. As long as India depends on multinationals for capital and technology. India will continue to rely on the imported technology of the United States.

Of course, in addition to the monopolisation of technology by the United States, the gap in the absolute amount of expenditures and the percentages to the gross national product (GNP) in Research and Development between the United States and India, 34 billion dollars, or Rs 26,000 crore (3.4 percent of the GNP), and Rs 150 crore (0.43 percent) respectively in 1971-72, perpetuated the existing US hegemony in technology [Banerjea 1975: 190-191].

As such, the technology of the United States, which was not available in India, became attractive to Indian professionals, including physicians, who wanted to pursue further research and training. Several surveys do indicate convincingly that professionals who leave their countries and live in the United States permanently do so largely for the research facilities and logistical supports available only in the United States [Oh 1977; Cortes 1974].

However, it was not only individuals who sought US technology but institutions in India as well. This point needs clarification since India, from its colonial period, modelled itself after the United Kingdom. Yet, as the United States came to lead the world in technology, US influence on Indian educational and research institutions became apparent. A typical example was the Indian Institute of Technology, Kanpur, established through the assistance of the United States [Sreenivasan 1978].

In relation to the medical field, the case of the All-India Institute of Medical Sciences was notable because it received 6 million dollars for its construction from the US government. Among private foundations concerned with public health and medical research, the Rockfeller Foundation was most active with its grant to the Indian Association for the Advancement of Medical Education [Sodeman 1971: 168-170], and provision of funds for teaching and research equipment to many medical colleges and institutes in India. Family Planning was clearly a very important project of the Foundation [Mukherji 1978: 170-71].

The introduction of US methodology and equipment for teaching and research no doubt led individual students and graduates to seek higher education in the United States. Also, needless to say, studyabroad programmes encouraged by the Indian government were another factor. Ironically the purpose of absorbing and importing western technology through the study-abroad programme was not well achieved due to the large number of students who did not return home.

The fact that graduates of elite institutions, such as IIT Kanpur, went abroad and returned with prestigious positions, suggests that, although these graduates were not

emigrating, they played a role in perpetuating the trend of modelling the educational system in India along the lines of educational institutions in the US. Naturally, in the case of FMGs, there was an expressed concern in the United States regarding the purchase of pharmaceuticals and equipment by other countries (including India) through FMGs. This meant, when FMGs returned to their home countries, it was expected that they purchase and introduce products from the US into their countries [US Select Commission on Immigration and Refugee Policy 1980 : 216-217].

In regard to the cultural aspect of migration, the 'colonial' mentality which was formally created through British rule in India should be considered. That is, in India, the British educational model was considered superior to that of the Indian [Munjee 1975 : 17]. A similar attitude was reflected towards US culture after the decline of British influence in India. This indealisation of western culture ignored or downgraded the culture of India. Thus it could be understood why the foreign-educated were considered superior in their fields in India even though they might not have had efficient skills [Munjee 1975: 17]. In looking at the 'neo-colonial' relationship with the United States, the attitude, although difficult to measure, is significant. It is well-known that the 'demonstration effect' which came forth with the influx of western goods stimulated Indian minds. On the other hand, those who went to affluent societies such as the United States became accustomed to the small conveniences of the United States, and thus, did not return [Daendekar 1968: 215].

In addition, 'neo-colonial' ties with the United States contributed to the emigration of Indian phyicians through the network of Asian Indian communties in the United States, and the information flow between India and the United States. For instance, the Directory of Approved Internships and Residencies by the AMA played a significant role in informing FMGs of the opportunities in the United States [Stevens et al. 1978 : 95].

In sum, the United States, backed by an overwhelming flow of capital goods, technology, and information, intervened in India's own economic development and incorporated India within its sphere. With an understanding of this relationship, which was not equal in nature, reasons behind the migration of Indian physicians to the United States can be seen.

Conclusion

In conclusion, it should be emphasised first that the phenomenon of migration is not a separate issue from interdependence under unequal terms between DCs and LDCs. In the case of India, the United States, replacing the United Kingdom after the late 50s, exercised an overwhelming influence on India through the movement of capital, goods, technology and information into India. This hegemony of the US over India began to incorporate India within the US sphere. This linkage is the very factor for understanding the exodus of Indian physicians to the United States.[13]

In this respect, international migration can be considered as an analogy to internal migration because after the influx of urban capital and system of production into rural areas, people were pushed out. Today, a similar relationship is exercised at an international dimension. Indeed, the movement of people from LDCs to DCs plays a role in establishing an international division of labour, while still other factors of movement, capital and technology, occur in an opposite direction, as earlier mentioned.

It should be stressed also that DCs are very much responsible for inducing migration from LDCs for the sake of their economic development, and whenever the situation changes, they are able to limit the entrance of immigrants. It is the DCs which have the option to open or close doors to immigrants, and the LDCs and individual immigrants must rely on DC policies, even though individuals may profit from the migration. Thus, the issue of the contribution made to the development of DCs by the international migration of high-level manpower from LDCs has also been discusssed, a phenomenon referred to as the reverse transfer of technology [Kabra 1976; Mainstrean 1974]. Indeed, generally speaking, freedom of mobility is widely acknowledged; however only the freedom to leave countries is granted, the freedom to enter countries is not.

Notes

[This study was partially funded by the institute of American Culture, UCLA, to whom I am grateful. I am particularly indebted to Don T Nakanishi, professor at UCLA, for his helpful comments on parts of this paper. It is needless to say that many of my friends at the Asian American Studies Center provided me with stimuli for this study. Also, I need to mention that the research assistantship at the Center under the auspices of Lucie C Hirata and Edna Bonacich, professors at UCLA and UC Riverside respectively, provided me with various opportunities to further my interest in this field. Finally, I am thankful to two editors of the South Asia Bulletin, Sucheta Mazumdar and Vasant Kaiwar for their comments and encouragement.]

1. As part of my project, I have done another case study on Pilipino. See Ishi [1982].

2. For a critical review of previous literature on international migration theories, see Bach [1978] in details.

3. For an overview on Indians abroad, see Tinker [1977].

4. According to Oh [1977: 33], the estimate of the non-return rate of Indian students was 59.5 per cent.

5. Regarding the problems faced by Asian health profesionals in the United States, both California and New York State Advisory Committees to the US Commission on Civil Rights made efforts to address the needs of Asian health professionals. See US Commission on Civil Rights, California Advisory Committee [1975] and New York State Advisory Committee [1980].

6. For a historical development of immigration laws in relation to manpower concerns, see Awasthi [1967] in details

7. Chen [1980] describes the background of the Immigration and Nationality Act of 1965 in respect to who pressured its passage.

8. The various methods used by Mathur [1971: 80-81] to estimate the supply and demand of doctors are as follows: 1) Supply was estimated from the assumption that no new medical college would be added, and the annual intake capacity of 15,000 would be fully met. 2) Demand was estimated a) from doctor/population ratio norms, b) the relationship between stock of doctors and the growth of national income, c) the relationship between demand for doctors and the stage of economic development-the fitting of the regression curve of doctors on national income to the data of different countries, and d) the component approach.

9. Cited in Pandit [1968: 109]. Also, in Reddy [1974: 375] cited that the Financer Minister of India in 1968 said the brain drain was not a loss to India.

10. The trend of increasing remittances countinued after 1975 when the incentives for non-resident Indians to invest in India were taken by the government [Rele 1976: 270].

11. According to a survey, approximately 60 percent of the Indians in metropolitan New York area send remittances to relatives in India of 100 US dollars or more per month [Thottathil and Saran 1980 : 245].

12. The following argument is based on a study by Ito [1972] in respect to Indian economic development after the second world war.

13. The study on the migration of Indian physicians from India to the United kingdom and the United States, and of British physicians from the United Kingdom to the United States, should be fascinating. Along with the US hegemony on research and development, and the establishment of a national health service system in the United Kingdom, many UK physicians went to the United States while many Indian physicians filled the shortage in the United Kingdom partly caused by the exodus of UK physicians. However, Indian qualifications were only recognised up until 1975. Afterwards, it became difficult for Indian physicians to emigrate to the United Kingdom [Smith 1980: 1-12]. In 1976, the United States also imposed stricter requirements as mentioned in this paper.

Undergraduate Medical Education in Underdeveloped Countries: The Case of Pakistan

s akbar zaidi

The type of medical education of a country is closely linked with its system of health care. Any health care system, with its own peculiarities, requires a certain type of doctor who can function effectively in the given environment. The same is the case with underdeveloped capitalist countries, such as Pakistan, where a skewed, elitist, curative model of health care exists. In Pakistan, where the literacy levels in the native tongue are very low, medicine is taught in English, and nearly all prescribed textbooks are written in and for the West. Conditions specific to Pakistan, such as the degree of cheating in exams, the time lost due to closure, and the level of debate concerning the medical system may find their parallel in other UDCs. Since it is the social and economic forces, which in the final analysis, determine the system of health care and medical education, one cannot expect any significant improvement within the existing class structure. (Reprinted from *Social Sci. Med.* Vol. 25, No.8)

THE historical evolution of most underdeveloped countries (UDCs) has resulted in a pattern of medical and health care which is, to a great extent, modelled on that found in developed countries (DCs). A salient feature of this type of health care is that it is essentially curative in nature. However, as the degree of social and economic development in UDCs still lags behind that in the DCs, the resulting model of health care is of a peculiar and distorted kind, and is in most cases, not as successful as that found in DCs [1-8].

The main feature that has evolved from this (curative care) type of health structure is the dominant role of the doctor in administering medical care. The preferable pyramidal structure for health personnel, where there should be more auxiliary health workers assisting each doctor, is in most UDCs, inverted [5, p 18]. These doctors have thus become the 'frontline' health workers, whether they function at urban hospital or district level. The role a doctor performs in any society is determined by the system of health and medical care in the country, which in turn is largely determined by the socio-economic formation prevalent there. Furthermore, the model of medical education, the process through which doctors are produced, is tied in very closely with the model of health care in that country and with the demands and perceived needs of the people or their ruler. If the model of health care in a capitalist UDC is one which is urban-based, hospital and curative care oriented and determined by the workings of the market mechanism resulting in a small minority of the population having any feasible access to the system, the doctor will go through a number of years of medical school so as to be able to work effectively in such an environment.

In socialist oriented countries, attempts will be made to make the doctor's role radically different and to involve him in social and community oriented health projects. This, however, is easier said than done, and a mere desire is not a sufficient condition to fulfill such political tasks. Given the fact that the medical education system before social change in these UDCs was one governed by the old socio-economic formation, the new socio-economic formation may not be able to bring in a new radical programme for medical education overnight. Clearly, the superstructure and its parts will take much longer to change than will the base. Nevertheless, a revolution in society will have its affects on the health system, which, as experience from the world in the last 40 years shows, will be greatly improved and expanded. For example, almost all socialist countries have made impressive gains in the health status of their people, thanks to the programmes of basic nutrition, housing, sanitation, water and education which now reach a majority of the population. Thus, physicians in these societies will be *aided* by the expanded health infrastructure in their attempts to eradicate disease. This advantage is clearly lacking in capitalist UDCs.

Furthermore, there is a difference in the position of doctors in the health system's matrix in capitalist and socialist UDCs. In capitalist UDCs, the doctor *(and thus medical education)* plays a more dominant role since supporting health infrastructure are lacking. In socialist oriented UDCs, other factors in the health matrix begin to play an increasing role. That is not to belittle the role of doctors and the importance of medical education in socialist oriented UDCs. Experience from these countries shows that by realising the importance of the role of doctors, concerted efforts are made to change the medical curriculum and to produce doctors oriented to the needs of the local environment. However, as has been argued above, the results may take time to bear fruit, as remnants of the old system may cause hindrances.

This paper will examine the issues relating to medical education in UDCs. After a brief overview of UDCs in general, we will turn to the particular case of Pakistan, a post-colonial state, and critically evaluate the system of medicine and medical education in this country. The final section will deal with the possibility of reform in medical education.

Health Care and Medical Education in UDC's[1]

A great deal of literature exists which deals with the model of health care in UDCs [1-22]. Most of these authors have limited their analysis directly to the model of health care, and have only indirectly approached the question of medical education. However, as we have argued, the two are very closely related.

Most of the present UDCs were, at one time colonies of the western nations. Their economic and social systems have been greatly influenced by the colonialists and despite their 'independence' they still follow closely norms and regulations left behind by their masters.

When the colonialists first took over, the overall society and economy of these countries were transformed, and the medical and health facilities were brought in line with the changing 'super-structure'. The colonial administrators required a model of health care which would cure the ills of their own people, their military and their bureaucrats. They thus set about 'importing' medicine from their home country and actively built up this 'western' type of health care, usually at the expense of the indigenous system which had existed earlier. As a select few of the locals were incorporated into the closed circles of the colonialists, a new elite was formed. Members of this small clique were also able to afford some of the luxuries brought by the westerners, one of which was the access to western medical care. When the colonisers left the foreign lands, the local elite had been so 'westernised' that they emulated their masters in practically all fields [1, 7].

The pattern of health care that has evolved in most of the capitalist UDCs is one based on curative care, and the workings of the socio-economic and political systems are such that health care has come to cater essentially for the rich and the elite [2, 8]. This model of health care has a predominantly urban bias in the distribution of facilities, and thus the majority of the population, usually rural, are denied the right to have access to health care [15]. And, it is not all the urbanites who have access to health care. Since medical and health care is sold like any other commodity in the market, most of the urban poor cannot afford the escalating costs of medical care either. In underdeveloped capitalist countries, we have argued that the socio-economic system, with its resulting class structure is largely responsible for this type of urban based elitist model of health care [8]. This model, along with a general low priority given to health care and disease elimination is responsible for the very high communicable disease pattern in these countries. However, there are a few UDCs which have at least made sincere attempts to solve the problems of their people.

The cases of China, Cuba, and Nicaragua are worth citing. In all these countries, there has been an improvement in the health status of the population. The infant and child mortality rate have fallen, facilities have come to be more equitably distributed, health services are free etc. [2 27], Mozambique too, is following a similar path and in dications show that the health status of her population i also improving [28]. What is important to point out her is that these countries have not only had a change of gov ernment, *but there has been a substantial transformatio in their economic structure*. They have gone from a no socialist mode of production (form of the economy) to socialist one, where the distribution of power and re sources rests with the people and their true representatives The people have collectively been able to decide what i best for them and have taken action for their own better ment and welfare without having to confront a hostile rul ing class. This importance of the change in the mode o production has been emphasised by Navarro as he argues "abundant empirical evidence exists to show that the mos important changes in the health of the underdevelope countries' populations during the last 20 years have oc cured in revolutionary Socialist underdeveloped countrie via changes in their economic, political and social struc tures, independently of and outside the health care sector [11, p. 169].

In underdeveloped capitalist countries, for the function ing of the inequitable and elitist model of health care, th medical college has provided just the right graduate: doctor who can function within the norms as defined b that society. Just as the economy of a UDC is closely tie in with the larger movements of the international econ omy, and is dependent on the developed countries, so to is its system of health care. Similarly, the medical colleg is linked closely with the pattern of medical education i the dominant (often ex-colonial) country. This is despit the fact that the real needs of the UDCs, as defined b their disease patterns and limited resources, are differen from the DCs.

Even in Tanzania after the Arusha Declaration, the cur riculum in the medical schools 'mimicked' that of th West with a content which is clearly unsuitable to th needs of the local environment. A major factor whic determines the need to achieve an 'international' standar is the faculty. This desire for acceptance by university authorities in the West, forces them to adopt western con cepts of 'academic standards'. The result is that "much o the curriculum is thus objectively being determined from outside the country" [16, p 47; also see 6,8]

Gish [14], Gish and Godfrey [19] and Horn [18] have shown how this type of western-oriented medical educa tion results in a 'brain drain' of professionals to the devel oped countries. Gish and Godfrey argue that due to in equities in the functioning of the market, medical care i also skewed in a manner which suits the rich. The pro spective doctor goes through an institution "whose 'stan dards' are generated by New York and London and ar mostly unrelated to the problems and possibilities o UDCs" [19, p 6]. The reason for this is that the bourgeoi

ie, who controls most of the resources in a country, requires the latest and best in medical care and thus try to roduce 'comparable' doctors at home [2]. This internaionalisation of doctors only helps the developed countries. The migrating doctors subsidise these countries as they do ot have to go through the expensive process of producing heir own doctors, while the social cost of producing them s borne by the poorer UDCs.

Not only does this internationalisation assist migration, ut by maintaining foreign standards, severe internal disortions also arise. Since medical students are taught their raft in hospital settings, as is done in the West, they often fail to interact with 'communities', both urban and ural and thus remain ignorant of the social causes of disease. Since the disease patterns in UDCs are quite different from those in DCs, the way to deal with them must lso be different. Medicine taught in the hospital setting is often not sufficient to deal with the complexities of disease in UDCs. The unfortunate outcome of this type of medical education is a hospital-oriented doctor who has been taught to function in urban settings with the help of modern and sophisticated technology. With such technologies and facilities lacking in rural areas, a large number of doctors would choose not to go there, thereby denying the right of the rural population to have access to doctors. With the concentration of doctors and facilities in urban areas, the limited finances of the health budget are spent here, where only a minority of the population lives [8,20-22].

A factor closely linked to the functioning of urban based doctors having a primarily curative approach, is the prescribing of drugs in great abundance. Since medical care, as it is practised, is linked with the doling out of medicine, this type of doctor and health care model also contributes in supporting the drug industry. The drug industry in most UDCs is foreign owned and acts as a further link in the exploitation of the UDCs by the West [29. 30].

Another important aspect of medical education has been lucidly examined by Banerji [1, 6, 7]. He says that in the course of their medical education, the students "who mostly belong to the upper classes, get further alienated from the masses of the people" [7, p. 33]. The colonial character of the health services, affecting medical education, also played its role in "shaping the value system and the social outlook of the Indian physicians" [1, p. 1334]. This class based alienation makes them further dysfunctional in the UDC, especially in the rural areas and urban slums, where due to their class position, they are often not able to relate to the poor. The doctor thus produced cater primarily to the elite of their country, or then, go off to the West or the oil-rich countries where they feel more at home professionally (and often even socially)[2][21].

This 'western' model of health care and medical education has been uncritically adopted by most UDCs. Thus the case study presented below, although specific to Pakistan, will clearly echo the situtation prevalent in other UDCs.

Case of Pakistan

Up to 1947, what are now India and Pakistan, were one country ruled by the British. Any history that they had until that time, was broadly the same, albeit, regionally specific in character. In the field of health services too, this is largely true with the exception that what is now Pakistan, had a greater influence of Muslim and Arab culture than did present-day India.

Debabar Banerji is a leading authority in the field of social aspects of medicine in the sub-continent. He has written extensively on the historical evolution of medical and health facilities in India and has shown how British imperialism imposed its values on Indian society and trampled on the indigenous health system that had existed until then. The colonialists developed their own system of health care (the 'western' system) and recruited a select few of the local elite to take over the entire political and administrative system after they left in 1947 [1, 6-8].

The resulting medical and health services system inherited by Pakistan is one which is modelled on the West (in particular Britain), being primarily hospital-oriented and based in cities. More than 90% of health facilities are in urban areas and the disparity shows no sign of improving [8]. The medical colleges in the country centre around this hospital-based approach to health care and look towards New York and London for guidance and inspiration.

There are at present 17 medical colleges in the country[3] with an annual intake exceeding 4300 students (there are at present more than 22,000 students enrolled). Two of these are exclusively for women while all the others are co-educational. There has been a great increase in the number of medical colleges in the last decade mainly due to the populist rhetoric of the Bhutto Government— in 1971 there were only seven medical colleges in the country. Some of these colleges were set up purely on political expediency, in cities which lacked even supporting infrastructure (eg Nawabshah, and Larkana—Bhutto's home town). Due to excess production, the present government has not only put a stop to the increase in the number of medical colleges, but has also decided not to increase the admission capacity of the existing colleges. *Ad-hoc* and anarchic policies, usually short-term, appear quite regularly, and despite weighty five-year and annual plans, there is seldom, if any, planning at all.

The curriculae of all the medical colleges in the country are identical and the colleges come under the aegis of the Pakistan Medical and Dental Council (PMDC). This body, apart from regulating and streamlining medical education, also looks at the ethical aspects of medical practice

Table 1: Allocation of Teaching Hours to Various Subjects in Medical Colleges in Pakistan

Serial Number	Subject and year	Total number of hours	Percent	When examined
Years I and II:				
1.	Anatomy with histology	800	24.5	1st professional
2.	Bio-chemistry	200	6.2	1st professional
3.	Physiology	600	18.5	1st professional
4.	Human relations, sociology, community orientation, medical ethics	100	—	—
5.	Pakistan studies and islamic ideology	100	3.1	1st professional
Year III :				
6.	Pharmacology including therapeutics	300	9.2	2nd professional
7.	General pathology (microbiology parasitology)	300	—	3rd professional
8.	Forensic medicine and toxicology	60	1.8	2nd professional
Years IV and V :				
9.	Community medicine (IV year)	100	6.2[1]	3rd[1] professional
10.	Medicine including applied physiology	145	4.8[2]	Final[5]
11.	Surgery including applied anatomy	145	5.1[3]	Final[3]
12.	Orthopaedic surgery	20	—	—
13.	Obstetrics and gynaecology	80	2.5	Final
14.	Paediatrics	50	1.5	—
15.	Opthalmology	30	0.9	Final

and acts as a control on malpractices. The body consists of senior professionals in bureaucratic positions and the principals of all the colleges. For all practical purposes, the PMDC does little work that is of any profound significance to the system of medical education. However, it does exercise some control over the curriculum of the medical colleges and determines the courses to be studied. The last major change occurred in 1975, when the PMDC laid down the present curriculum for the MBBS degree. Since then some insignificant changes have been made, notably in the shifting of the subject of community medicine from one year to another. Another recent change is the introduction of Pakistan Studies and Islamiat (Religious Studies) in the first year of medical school [31].

Education in a Medical College

A student enters medical college after 12 years of schooling, the last four of which have already determined the choice of the student (or in most cases, his parents') towards medicine. However, a miniscule proportion of those who in their ninth year of school opted for medicine eventually get to medical college. Further, admission to medical school is not limited to merit, as a quota system exists which permits some second class students to enter.[4] Thus competition from an early age is fierce, and only those who excel, or have the right connections, or right regional or social backgrounds, are admitted.

The medical degree, MBBS, is spread over five years with four professional exams. Years one and two constitute the course work for the first professional exam, with a professional exam each year for the remaining three years (see Table 1). Clinical teaching starts from the third year, where students are supposed to spend 2 or 3 hours a day for a period of nine months with one month per ward. The third year group is taught how to examine patients but is not given lectures on diseases and is largely selftaught. Attendance to the wards is compulsory, as it is to classes, but as the group gets larger because of bigger intake, it gets more unmanageable and as learning by the bedside gets more difficult, more and more students stay away. Eventually only the core group of bright and eager ones remain, while the ones with lesser competence who need more attention stay away.

Community medicine is rarely given much importance

in UDCs, and Pakistan is no exception (see Table1). Previously, there used to be 'field trips' in the subject which took students to see sewerage plants, rural health centers, and other such institutions. Even then, community medicine had a 'curative' institution bias. Rarely did the students interact with a 'community', whether urban or rural, and often these trips were considered 'fun trips' and 'outings'. Now this procedure has been replaced by discussions and seminar groups for a period of one month each year. Thus, the discussions by the alienated students relates to 'communities' of which they have no first-hand knowledge. Due to a lack of training in the social sciences, they are also unable to see the social mechanisms at work in the environment. Even the patients that come to the wards are usually from urban backgrounds, so exposure to rural disease patterns is totally lacking [20, 21].

Further, the students are not taught in detail about common diseases such as typhoid and malnutrition, but instead, surgery, pathology, etc are emphasised. The students are advised to specialise in subjects which offer lucrative returns. A post-graduate in community medicine may be more qualified to deal with diseases in a poor rural community, but he would indeed have a hand-to-mouth existence. There is no social value attached to community medicine in this society and little or no demonstration effect exists. Thus, for students to reject community medicine and specialise in neurosurgery is sad, but nevertheless, understandable.

Lending facilities in the college libraries are poor and so students have to buy most of their books. Nearly all books are written by western authors and thus are fairly expensive, although now most of them are printed in Pakistan, or published in the Far East. In the first year a student is required to buy the greatest number of books which are also the most expensive. 'Gray's Anatomy' alone costs close to Rs. 700 and the bare minimum cost for books in the first year comes close to Rs. 1700. If a student wishes to purchase medical 'atlases', he must spend a great deal more. Further, the desire for 'latest' books means that since editions change very fast and the material changes as well, students cannot usually work with second-hand books from their senior colleagues. By the end of the final year, the students have spent between five to seven thousand rupees for their very basic books and if they want a few more necessary texts, they must spend further Rs. 3000-4000. The costs in many individual cases can be substantial.[5]

At the end of the five years in medical college (which in Pakistan due to 'disruptions' usually extends to seven),[6] the students are supposed to do a 'House Job' (internship) for a period of one year. Six months are spent as a junior, while the other six are spent as senior house officer in the same or another speciality. Again, the opportunity to work in a certain ward is based on merit, with about 30-40 doctors per ward. Of these only a few are paid, while the rest must be honorary.

The basic issue with which we start our criticism of the model of medical education is that of language. The medium of instruction in all medical colleges in Pakistan, is English; Pakistan, like India, is a country with different nationalities and cultures, each region having its own corresponding language. Although the official languages are English and Urdu, the entire population cannot speak Urdu, leave alone English. The regional languages have preference over the official ones, especially in the interior of all the four provinces. Further, only 26 percent of the population is literate (in any language). Thus, of those 26 percent one can presume that very few would be able to read and write English. Even fewer would have English as a mother tongue. Moreover, although medical education is in English, schooling can be in any regional or national language. A student may speak his mother tongue at home, he may use another language for primary and secondary education, and yet a third for professional education. That means that although a student has spent 12 years of school life in a language other than English, he or she will be confronted with a 'foreign' language once he enters medical college. This foreign medium of education means that very few students from per-medical schools will actually be able to learn much in medical colleges. This preference for English shows a bias towards the elite and westernised urban based minority who are accustomed to English in their homes and educational institutions. Members of this elite, apart from being able to learn more, and with much more ease, claim the best house jobs, followed by the most lucrative job offers. Thus, discrimination on a class basis is reinforced through the medium of instruction in medical colleges. Further, if medicine were taught in either the regional or national language, the international mobility of doctors would fall dramatically. This is a situation which the elite, whether doctors or laymen, will not readily accept [21].

The problem of language is not restricted to the lecture halls alone. Students have to take histories from patients, if not in the mother tongue of the patient, then in the local or regional language. A student who does not even know the names of the most basic diseases in the national language, will have substantial difficulty in finding out what is bothering the patient. There will be very little communication between the two, if at all. Langauge, however, is only a minor barrier compared to the cultural barrier that exists between the patient and doctor. In most post-colonial societies, a separate 'culture' exists for the elite, and even a mastery of the language will not necessarily close the cultural gap between the two [21].

The books that are used in medical colleges in Pakistan are in most cases written by foreign authors—mostly American and British.[7] These books cater, primarily, to a western audience in medical schools in developed countries. They are written in, and for, a specific socio-eco-

nomic culture and environment dealing with a particular health and disease pattern. The fact that they are used in UDCs without any changes, causes a few problems. Since the authors have the DC student in mind, quite naturally they talk more of diseases found in the West than in Pakistan or other UDCs. The main diseases in Pakistan which are caused by infections and are communicable have more or less been wiped out in the West. Further, a great number of diseases in UDCs have their roots in social and economic conditions which are far removed from the hygienic western hospitals in the countries of the authors. Thus, some diseases which are very common in Pakistan, such as typhoid and diptheria would be treated as 'interesting and rare' cases in the West, and would not be given the importance they deserve in the texts.

The average size of a class in medical colleges exceeds 250 students— in some colleges it is more than 400.[8] With such an unfavourable student-teacher ratio, it becomes very difficult to learn anything in class. Further, the audio-visual facilities that exist in all medical colleges are very poor, and thus most of the students are in effect, not participating in the learning process.

One important factor which upholds the existing system of education is the role of the teachers. With very few exceptions, all are foreign qualified. In fact, it is very helpful for teachers to be foreign qualified if they intend to rise to the post of professor.[9] These tutors lead their students through the course they went through— first education in Pakistan, followed by essential foreign training to learn the latest teachniques. These students if they come back, either end up in large hospitals in the city or else attempt to go and settle abroad where lucrative jobs await them.[10]

The irony of the medical education system is that with 4000 new graduates a year, not all can be absorbed in the existing health system. This leaves many unemployed, and the numbers keep on increasing at a very fast rate indeed. This expanding cumulative unemployment arises despite the fact that very few people in rural areas have access to doctors who tend to converge in the more lucrative urban areas. The medical education system has taught the doctor to deal with sophisticated equipment and modern technology. In a rural area he is completely lost without his tools. Further, the disease pattern is also different, and he may find that unless he is aware of rural sociology, politics and economics, or is a native of the rural areas, he will not be able to function effectively [8, 13, p. 217, 20].

The examination system in medical colleges acts as a major contributor to the poor quality of doctors produced. With the emphasis on essay-type exams held at the end of the year, with journal work and orals (viva-voce) playing a small part, irregularities are quite widespread.

It is not possible to assess exactly the amount of cheating, but one can, on casual observation, clearly see that it is quite significant. One observer quoting medical students, wrote in a local newspaper: "there was a question on typhoid ... we ignore small items. We prepare diseases which have complex, lengthy treatment so we could fill up pages. Typhoid has a simple treatment. Nobody bothered to study it. We strongly protested (to the invigilator) and cheated, of course" [32]. (This happens where every third day, six or seven cases of typhoid turn up in the wards). It is estimated that as many as 90 per cent of the students cheat. Cheating is not only limited to written exams, the oral exams, which should be a safeguard against cheating, are also subject to unfair means. There is a case where a student got a distinction in a subject by giving his tutor a diamond. Other students have been known to arrange for foreign trips for their teachers, while still others have paid for the petrol of their teacher's car for the whole year. Cheating in educational institutions of all types, at all stages is epidemic, yet few active measures are taken to deal with the problem.[11]

There is an anomaly which is probably unique to Pakistan. Some medical colleges in the country, although functioning under the PMDC regulations are not recognised. The degrees of the Chandka Medical College, set up in 1972, are as yet not acceptable to the post-graduate medical centres of the country. Two other colleges which have been functioning for a number of years have only recently been recognised. This essentially means that a student may complete five years of medical school and yet be legally unable to practice medicine.[12]

The present government of Pakistan has repeatedly played the nationalism and religion 'cards' as a means to extend its rule in the country. It has thus introduced the subjects. Pakistan Studies and Islamiat, in the curriculum of medical colleges. In fact, of all subjects taught in the first year they are probably the most important. If a student fails in either of the two he or she will not be allowed to reappear in the subject and will be declared failed in *all* subjects. Apart from the argument that religious studies have nothing to do with medicine, the level of instruction in these two subjects is similar to that of intermediate (class XI and XII), and is thus a repetition of the previous years. However, in this case, they not only add to the burden of work, but with so much importance granted to them, cause unnecessary anxiety.

Although the problems mentioned above may be specific to Pakistan, many UDCs can find some similarities. However, the level of debate concerning reforms in the medical system in this country, is of a very poor standard compared to other UDCs, such as India.

Since health care itself is not considered an important priority of the government—the health sector gets only 0.6 percent of GNP—any issues related to problems within the health system receive even less attention. Very little research is done in Pakistan which deals with problems related to medical education. Nevertheless, a few

government publications do exist which indicate the attitude of the doctors and concerned bureaucrats. However, since they echo the elitiest bias in medical thought, the recommendations if followed, can prove quite disastrous to the welfare of the masses of the country.

A commission set up in 1960 (33), to study the medical and health sector came up with some recommendations dealing with medical education. Some salient points of the report are worth noting.

The report recommended that "since children of medical practitioners will have seen at first hand what will be expected of them by the community, therefore a bias towards the children of medically qualified parents (in the case of admission to medical college) should be exercised" (33, p. 46). Such an attitude is reflective of the medical lobby which wishes to perpetuate its own hold on the profession. The prominent professors and physicians who control the health system wish their offspring to enjoy the fruits which they have tasted. The class nature of medical professionals is thus further re-inforced. (21).

This is evidenced by another recommendations which accepts the fact that many students' "knowledge of English is insufficient for them to profit from their course of studies" (33, p. 56). Rather than suggest a conversion to the mother tongue of the students, the writers of the report urge the teachers in medical schools to give their students "practice in speaking, reading and writing English" (33, p.56). The elite, who are fluent in English and need no 'practice', would nevertheless have an upper hand in the system.

The elitist bias is further revealed by the fact that the report gives only four lines out of 20 pages to community medicine. This is so because the elite amongst the doctors are the last who will need to see a rural community or an urban slum, since most of their clients will be well-to-do urbanites. Thus even if they were taught community medicine, they would have little opportunity to put it to practice.

The western-orientation of medical education in this country is further reinforced by the recommendations of the report. It suggests that the more 'enterprising' men and women who can make the 'necessary arrangements' should complete their training in the United States or Britain. In fact, another report goes even further.

Ahmed (34), argues, that not only should the physician training programme maintain international standards of quality, but since the cost of producing medical personnel is low, the world price is high, "the setting is ideal for developing an export market" (34, p 12). The object of medical education, according to the author is to "produce a graduate within our resources who is accepted internationally" (34, p. 13). (The report was funded and published by the Public Health Association of Pakistan!)

There exists little consciousness about social issues in this country, either at the political/bureaucratic level, or at the mass level. Further, with a dictatorship at the helm of government, any semblance of debate and dialogue if it gets underway, is heavily biased in favour of the existing status-quo. The media is totally controlled by the government, where inhabitants of the country are given their daily dose of 'newspeak'. With such an atmosphere existing within the social conditions of the country (lacking any significant opposition), any reforms that take place will be similar to those mentioned above. They will be totally cut off from social reality and will at best be only 'cosmetic'. Thus, to await reforms from the ruling class to suit the masses, is both native, and unrealistic. As long as 'things are in control'. and the status-quo remains stable, the government have no need to cater to anyone but to those whose interest it serves.

Possibility of Reforms

As the title of this section suggests, we will deal with recommendations for reform in the medical education system in UDCs. We will essentially deal with the suggestions put forward by Gish and Godfrey (19). We feel that their recommendations are indeed ideal and if followed through would result in an excellent system of medical education and health care which would fit the requirements of UDCs almost perfectly. As we proceed to show, however, their recommendations are good only on paper and as they have ignored the social and political forces active in UDCs, cannot be implemented in capitalist underdeveloped countries very easily.[13]

Gish and Godfrey start their paper with a critique of neo-classical reforms rejecting the framework on which they are based. Their alternative framework accepts an international market for professional skills into which UDCs are well-integrated. Their suggestion is a withdrawal from the market, essentially arising from a changed focus in educational policy which should deal with internal needs rather than external markets. They have presented some specific recommendations to which we now turn. (Their paper deals primarily with UDC commonwealth governments.)

The authors have given 11 different recommendations for UDCs which are summarised as follows: (i) an end to use of British qualifications; (ii) no more foreign professional examinations in UDCs and an end to advertisement and recruitment by developed countries; (iii) disaffiliation from western-dominated international professional associations; (iv) permission for students to go abroad only on 'relevant' courses. (v) the development of local courses and qualifications which are more suitable to local needs and thus less acceptable to the western employers— a 'de-internationalisation' of doctors and medical education; (vi) regional cooperation for higher education; (vii) the use of the national languages as the medium of instruction. (viii) improved rewards and job content; (ix) various controls to dissuade overseas study; (x) rejection of various, other

(outside the health sector) interests; and (xi) the restriction of the output of doctors in UDCs to the number that can be absorbed at home (19, pp 8-10).

Let us now proceed to examine each of their recommendations. Firstly, an end to British qualifications must take place not only at medical college level, but also at school level. At present the vast chain of 'O' and 'A' level schools all over the commonwealth offers the elite the opportunity to acquire British education while sitting at home. They have a great deal to lose by denying themselves this privilege and one sees no reason why they should give this up. Again, the author's second point: although Pakistan has ended the sitting of foreign professional exams in the country, those with money can easily fly to London or San Fransisco and take the relevant exams there.

Recommendation (v) requires substantial changes in the model of health care. Of course, UDCs should have locally specific courses so that they can function in the local environment, but again, as has been argued above in the way the class system exists, the rich want a certain type of doctor who is well acquainted with the latest and best techniques in major hospitals in the East, and not in the poor areas at home. It is quite clear that the doctor produced in UDCs favours and belongs to certain class, and this class, in all essence, determines the type of doctor to be produced and supports the 'international' curriculum (1,2,8,21).

Instruction in the national language, as we have shown above, also chips away the advantage of the elite for whom English has become a mother tongue. By introducing the national language (which is itself controversial, say in India), members of the lower classes will have access to the domain of the elite, again a hard-won privilege which they will not give up easily. Further, UDC governments can if they wish, discourage overseas study, but if a monetary mechanism is used, the rich can over-ride it. It seems doubtful that any other means will be used, especially since the children of the elite are the ones who are most likely to go abroad. Even local production cannot really be restricted, as the burgeoning middle classes will clamour for their rights as well.

Essentially, the above discussion looks at the relationship of the elite (the dominant class/classes) with the government. We argue that the dominant class has substantial control on the government and on the distribution of health resources in a country (2). Further, in the absence of any significant challenge or opposition, we see no reason why the ruling class should carry out policies to hurt its own interests. This is mainly what Gish and Godfrey have recommended—the government working for the 'masses' at the expense of the elite. This is clearly a problem in underdeveloped capitalist countries. However, in countries where there has been significant social change and mass participation and genuine democracy has resulted in the control of the people of their own destinies, these reforms are possible. Mosambique is an example of a country in which such change has occurred and it has carried out some of the reforms recommended by Gish and Godfrey. They have 'de-internationalised' their doctors, teaching them more about their own country than about the colonial nations. This has resulted in a more socially conscious, 'new' doctor, required by and suitable to the needs of Mozambique (28, 35).

We have analysed the issues involved in the model of medical education in UDCs, and have treated Pakistan as a case study. The factors that come out most clearly are that medical education is a reflection, in the final analysis, of the socio-political structure in the country.

The present form of medical education in capitalist UDCs is elitist in nature and is a major impediment to an equitable distribution of health care. This type of medical education, often in a 'foreign' language, favours the dominant classes and produces a doctor who works best in an urban-hospital setting either in the home country or in the West. Such a doctor is heavily incapacitated in rural settings, as he has not been trained in line with the needs of the country.

The case of Pakistan is peculiar in some cases, but in most of the broader issues concerning medical education, she is like other dependent UDCs. A lack of clear planning and the interests of those in power have often determined the path of medical care and the growth of medical educational institutions. The system of medical education is an important factor in the health care package and thus requires a restructuring to suit the true needs of the people. Clearly, mere rhetoric on the part of the government will fail to achieve this aim. What is essentially needed is a change at the political and economic level which will in turn affect the health care system and the system of medical education, and will thus determine new priorities. In a new society, a people-oriented package is to be devised, in which a newly designed medical education programme should play an important role alongside other ingredients of the health matrix.

[I am greatly indebted to Mehreen for her invaluable comments and suggestions. The editors of this Journal also deserve gratitude for some excellent comments on the first draft.]

Notes

Our discussion is stricted to underdeveloped capitalist countries and we have purposely ignored developed countries. It is true that in advanced capitalist countries health care is fairly well distributed and accesssible to all, but this is a different issue, and we believe that comparisons between DCs and UDCs (whether capitalist or not) are quite irrelevant and out of context.

2 It must be emphasised that it is not doctors who are at fault, but the class system by which they are produced and in which they function.

3 Of the 17 colleges, all but one are government owned. The Aga Khan University is the only private University in the country and is linked closely with McMasters, McGill and Harvard Universities. It however also follows PMDC regulations, but has the 'advantage, of not only foreign trained personnel, but expatriates on their faculty.

4 Each college has its own 'quota system'. A certain percentage of seats are given on merit, while the others are re-

served for the children of: Military personnel, ex-service men, employees of the Education Department; and for students who have done well in extra-curricular activities and for students of underprivileged areas (these are usually termed 'rural' seats).

5 Ussi=Rs. 17/- annual per capita income in Pakistan is $335.

6 The colleges, due to local (college) or national politics and disturbances, are closed for many weeks each year adding up to a minimum of two years in a medical students college life.

7 About four of the 20 'essential' books are written by Pakistani authors. There is an unfortunate twist to this, in that the few books written by Pakistan authors are unfortunately of extremely poor quality, but are nevertheless, made compulsory if the author happens to be teaching the course.

8 The Army Medical Collge in Rawalpindi run on very disciplinary (military) lines, admits only 100 students a year. Liaquat Medical College in Hyderabad admits 447.

9 Of the 19 full professors at the Army Medical College, only three were not foreign qualified. The three are professors in the relatively less important subject of forensic medicine, biochemistry and physiology.

10 As many as 50 percent of doctors produced in Pakistan are abroad.

11 The author on a visitor to medical college found every student sitting in the corridors diligently working away. On no previous visit had the author seen students so busy. On enquiry it was revealed that each and every one was making notes to pass on to students in the examination hall.

12 The PMDC reiterates its claim that the level of teaching at these colleges is not up to 'standard' and thus their doctors are not 'properly' qualified.

13 Although Gish and Godfrey's recommendations are meant to reduce the exodus of physicians from UDCs, we feel that since it is the education system which causes the migration in the first place, their recommendations need to be discussed as they are extremely cogent and worthwhile.

Economic and Political Weekly

A journal of current affairs, economics and other social sciences

Every week it brings you incisive and independent comments and reports on current problems plus a number of well-researched, scholarly articles on all aspects of social science including health and medicine, environment, science and technology, etc.

Some recent articles:

Mortality Toll of Cities— Emerging Pattern of Disease in Bombay : Radhika Ramsubban and Nigel Crook

Famine, Epidermics and Mortality in India—A Reappraisal of the Demographic Crisis of 1976-78: Ronald Lardinois

Malnutrition of Rural Children and Sex Bias: Amartya Sen and Sunil Sengupta

Family Planning and the Emergency—An Unanticipated Consequence : Alaka M Basu

Ecological Crisis and Ecological Movements : A Bourgeois Deviation?: Ramachandra Guha

Environment Conflict and Public Interest Science : Vandana Shiva and J Bandhyopadhyay

Geography of Secular Change in Sex Ratio in 1981: Illina Sen

Occupational Health Hazards at Indian are Earths Plant: T V Padmanabhan

Inland Subscription Rates

Institutions/Companies one year Rs 325, Two years Rs 625, Three years Rs 925

Individuals Only: One year Rs 250, Two years Rs 475, Three years Rs 700

Defining Quacks

CONSUMER Week this year was celebrated by meetings organised by several organisations such as the Consumer Guidance Society of India, Grahak Panchayat etc on health and health related issues like medical care and quackery, responsible medical practice etc. While these are commendable efforts at consumer education, the process can never take off unless certain uneasy questions are confronted.

Is it enough to define quacks as those who do not have appropriate degrees and qualifications? Such practitioners are, of course, quacks. But there are also those who practise 'quackery' even though they possess requisite qualifications and degrees. These are the properly registered doctors who pursue irrational practices and therapy. We illustrate this with just two instances :

(a) Several surveys and our own experience shows that a majority of patients who approach doctors receive injections regardless of their ailment. Is this rational practice? Medically, injections are given only in three situations—life threatening conditions; when the patient has severe vomiting and cannot retain oral medication and; when the drug is not available in oral form, such as insulin. Aren't these doctors who prescribe injections indiscriminately also 'quacks' of a sort?

(b) Such quackery became even more visible during the recent controversy regarding high dose estrogen progesterone (HDEP) drugs. No standard text book of medicine or pharmacology recommends such HDEP drugs. Moreover, they are known to cause serious harm to the foetus when taken by pregnant women. And yet, this drug with a multicrore-rupee market was freely prescribed and used by doctors not only for pregnancy testing but even to induce abortions. Further, when the Supreme Court ordered a public enquiry to decide on whether the irrational and potentially harmful drug be banned, some of these doctors chose to give glowing testimonials in support of the drug. Is this responsible medical practice or is this 'quckery' to help the drug industry?

The Medical Council of India is charged with the responsibility of regulating medical practice which includes curbing quackery. What has it been doing? It has never come out against irrational practices such as the propogation of the 'injection culture' by doctors; it has kept a dubious silence on the issue of the doctors' role in pushing hazardous drugs; and even worse, it has not bothered to take action against the doctors which the Lentin Commission had named as being responsible, by their negligence, for the tragedy at the J.J.Hospital. One may legitimately ask: Is this a body to enforce medical ethics or a body to legalise quackery?

Of course, the MC does take prompt action on certain issues such as promptly de-registering a non-practising filmstar doctor for advertising. Or more recently, the Maharashtra Medical Council issued a statement 'threatening' the doctors who supported Dr Bal in his fight against victimisation with 'dire consequences'. His supporters, it will be recalled are agitating against the sinister role played by Dr Sudhakar Sane in his personal capacity as Vice President of the Managing Committee of Dhanvantri Hospital from where Dr Bal was dismissed. Dr Sane happens to be the current president of the Maharashtra Medical Council and so the MMC sought to provide protection for him for his personal ill-deeds.

Why was Dr Bal victimised by Dr Sane and his friends in the managing committee of Dhanvantri Hospital? Because he is the secretary of ACASH, a consumer organisation which along with others sought to get the HDEP drugs banned, started a campaign against the unscientific claims made to sell analgin by the industry and so on. Thus so-called qualified doctors and their premier body have chosen to victimise those who are fighting against the quackery of medical professionals.

It is really ironic and tragic that in the consumer week the president of the Maharashtra Medical Council was invited by the CGSI to speak on Consumer Education in Medical Practice. Not only that, the CGSI which supported Dr Bal and the drug consumer movement till recently has decided to dump both Dr Bal and the campaign for rational use of drugs in favour of such medically-organised quackery. We cannot help wondering at the kind of education that this protector of the high priest of medical quackery will give to lay people. In any case, do people who either indulge in this sort of 'quackery' or give them protection by refusing to confront the issues have any moral right to be part of consumer meetings? They are really the 'accused' and not the 'educators'.

Isn't it time to take the bull by the horns and confront the medical establishment with these issues?

(Press release from Medico Friend Circle, Bombay Group on March 18, 1989.)

Rural Doctors in Thailand

IN accord with a world-wide change in attitude about health services the government in Thailand has adopted a health policy centred on community services and a better balance between prevention and cure. However there are problems with the implementation of the policy. These problems were raised at a seminar held recently in Bangkok about the role of community hospitals in public health development. Jointly organised by the Rural Doctors' Association (RDA) and the Ministry of Public Health (MOPH), some 400 rural doctors attended the seminar.

The government policy, as laid out in the previous Fifth (1982-1986) and current Sixth (1987-1991) National Health Development Plans, talks of participation in development, basic minimum needs, primary health care, decentralization and intersectoral collaboration. Nobody disputes the soundness of the policy. And few would dispute the progress made to date. The number of doctors in the rural areas has more than doubled over the past six years. This year 63 per cent of the health budget will be spent on rural services, compared to 43 per cent in 1981. All villages have local village health personnel, and almost all districts have hospitals. In general, the government's policy is well approved of and is having some positive results.

The RDA though is critical of the actual implementation and argues that the potential positive effects have been hampered by a budget that does not adequately reflect the policy, and poor education for all health personnel about the principles of primary health care.

As already mentioned, over the past six years the number of doctors working in the rural areas has more than doubled. However as the chairperson of RDA, Dr. Supatra Sriwanichakorn pointed out, "This still represents less than 10 per cent of the more than 14,000 doctors nationwide while more than 80 per cent of the population are rural residents." Thus in the north-east of Thailand, the poorest region, the ratio of doctors per head of population in 1984 was 1:15,554 while Bangkok could boast a ratio of 1:1,321.

In addition to this only 45 per cent of these rural doctors have worked there for more than two or three years. The government currently requires medical graduates to work in a rural hospital for three years after graduation. Thus the majority are relatively inexperienced and rush back to the city after their compulsory rural service.

A further concern of several speakers at the seminar was the dehumanising effect of the modern medical system. Several speakers reiterated the need to inject 'spirit' into the practice of medicine. Contemporary medical education is often centred on accomplishing skills at utilizing medical technology, ignoring the inter-dependence of body, mind and spirit. Thus, training of all health personnel is inadequate in instruction on both the principles of primary health care and the dependence of physical health on social and spiritual well-being.

While it is true that considerable gains have been made towards achieving equity in health expenditure, further redistribution is essential if the health status of the poorest Thai people is to improve.

A former chairperson of RDA and now a member of the Health Planning Division, MOPH, Dr. Suwit Wibulphonprasert explained this further. "If the proportion of the health budget spent in rural areas, now a relatively fair 63 per cent of the total, is dissected further it can be seen that half of it goes to provincial hospitals and more than two-thirds of the remainder goes to district hospitals." Thus the vast bulk of the budget is used for hospital services.

Now is the time to concentrate on health services at sub-district and village level. The projected 9 percent increase in the 'district/sub-district' item of the health budget will almost all go to the sub-district level. There are plans to employ nurses in all the Health Centres as well as to increase the availability of Mobile Health Teams for weekly visits to the Health Centres. However, should this become merely an outreach extension of the hospital it cannot be considered a true diversion of funds towards primary health care.

The RDA is also advocating more autonomy of district hospitals so that decisions about implementation of policy can be made locally with local conditions in mind. Decentralisation is the key-word. "But you have to differentiate between delegation and decentralization" Dr. Suwit cautioned. Delegation is handing down the responsibility for some decisions from one officer to another. Decentralisation should go hand-in-hand with full community participation. That is, power should be devolved to the recipients of health services.

The Rural Doctors' Association is certainly not disputing the general direction of the government's public health strategy. They do believe though that much more could be done to accelerate the health development of Thailand— for all of its people.

Private Sector in Medical Care
(A Brief Survey)

rama v baru

The increasing penetration of high technology equipment is making medical care a profitable venture and has provided a fillip to the expansion of the private sector, which in health care comprise clinics, nursing homes, hospitals, pathological labs and diagnostic centres. What are the factors which have led to this development? What are the implications for health care?

WHILE only a few years back there were hardly any hospitals which offered super specialist services outside major metropolitan centres, now a large number of private hospitals and diagnostic centres have come up in all major cities. Some of these organisations are corporate enterprises which are run like regular business concerns by floating shares in the market. Big business groups like Tata, Hinduja, Modi and Escorts and regional groups like Standard Organics Ltd in Hyderabad and Apollo Hospitals Ltd. in Madras have diversified into Medical care

Whether in larger hospitals, nursing homes, diagnostic centres or pathological labs, high technology medical equipment like scanners nuclear gamma camera, lithotripers, auto-analysers and the like have come to play a crucial role for diagnostic and therapeutic purposes. Nearly 80% of all medical equipment is imported through companies like Siemens of Germany, General Electric of USA, Dornier and Hitachi.[1] Although equipment costs are high, imports are rising quickly. While in 1980 alone Rs. 20 crore worth of equipment was imported, by 1986-87 it had risen to Rs. 65 crores. According to an estimate, imports are expected to rise at the rate of twenty percent annually for the next three years. The trend of increase in import of high technology medical equipment is essentially a fall out of the liberalisation of procedures by the Government on import of technology. In the case of medical equipment the government has reduced import duties from 107 per cent to a mere 40 per cent. In addition, total duty exemption has been granted to hospitals and diagnostic centres willing to treat at least 40 per cent of their patients free of cost. In the case of non-resident Indian (NRI) investors exemption from import duties is granted if at least 25 per cent of the patients are offered free treatment.

The liberalisation of import duties coupled with increase in the income of middle and upper middle classes has resulted in the demand for consumer durables and luxuries. This, naturally, has had an effect on health care as well. A number of large projects have been initiated and several existing hospitals are being expanded and upgraded by business groups and private trusts across several States in the country.

According to a market survey report by a leading pharmaceutical company, in Uttar Pradesh, the Modi group of industries is establishing a super specialist hospital in Modinagar with emphasis on specialities like paediatric, cardiology and cancer treatment. The project is valued around Rs.200 million and is nearing completion. Apart from this several smaller projects have been initiated in major cities of North India. In New Delhi the cancer treatment facility for the 1000 bed All India Institute of Medical Sciences is being developed in cooperation with the Rotary Club of New Delhi. The estimated cost of this project is to reach over Rs. 100 million. In addition a number of large hospitals and diagnostic centres have also been set up with NRI collaboration in New Delhi.

A sizeable number of large private hospitals have mushroomed in States like Maharashtra, Kerala and Andhra Pradesh over the last few years. In Maharashtra, Bombay has three or four large projects in the offing. The Hinduja business family from London is funding the expansion and renovation of their 100-bedded National Hospital to a 300-bedded modern general hospital with the latest diagnostic equipment. The hospital proposes to offer specialised services in opthalmic and orthopaedic surgery.

The Indian Cancer Society in Bombay has initiated the construction of a new cancer hospital which is valued at Rs. 200 million. Yet another 200-bedded hospital is being built by the Mahavir Health Foundation which is a charitable trust. The estimated cost of this project is Rs. 100.50 million and will specialise in cardiac and kidney diseases. The Bhatia General Hospital which is run by a private trust in Bombay has been expanded at a cost of Rs. 20 million with super specialist service like cardio-therapy, ultra sonic imaging and clinical analyses equipment. The mushrooming of private hospitals in Maharashtra is by no means confined to Bombay. Karad town in Satara district of Maharashtra has a 200-bed private hospital started with an investment of Rs. 30 million to provide for construction and initial costs. Since the project is located in a small town it is expecting to provide services to surrounding villages as well.

In Kerala there has been a state-wide boom in private hospitals. According to a survey conducted by the Bureau of Economics and Statistics in 1986, there were 1,953 government institutions with a bed strength of 38,133 as against 3,585 private hospitals with 50,766 beds.[2] While cities like Trivandrum and Cochin have their share of high technology medical centres, it is by no means restricted to the larger cities. In fact high technology medical care has

penetrated even into smaller towns and villages, in some parts of Kerala. According to a report it is not uncommon to find private hospitals in villages having scanning and diagnostic cum therapeutic equipment being used for treatment of patients.

Apart from big business groups and private trusts establishing hospitals with sophisticated equipment, regional business groups have also entered this arena. Apollo Hospitals Ltd, a Madras-based corporate concern was one of the first to establish a super specialist hospital in South India. Recently, the same concern has initiated another project in Hyderabad with an initial investment of Rs. 12 million to cover construction and equipment costs.[3] Several such projects are being initiated in Andhra Pradesh by business groups and private trusts in collaboration with Non-Resident Indians. Standard Organics Ltd, a Hyderabad-based corporate concern has also made inroads into health care. The Standard Organics Ltd which is essentially a pharmaceutical concern has diversified into leasing of medical equipment and have set up diagnostic centres in several major cities in the country.[4]

In a recent announcement a group of Andhra non-resident Indian doctors based in California are initiating super-speciality hospitals project in Hyderabad, Vijayawada and Visakhapatnam. The cost of each of these projects is estimated at Rs. 30 crores and will consist of over 300-bed hospital, 200 nursing quarters, 100 physician quarters, a hundred room three star hotel, a thousand seater auditorium and four lecture halls. In addition to providing super specialist services the foundation seeks to "bring about medical and health awareness in rural and semi-urban populace through continuing medical education programmes with accent on rural health.[5] Apart from these large projects a number of smaller ventures have already been initiated in the several major towns. In Hyderabad a local business group has initiated a super speciality hospital valued at Rs. 7.60 crores is nearing completion.[6]

Calcutta is yet another metropolis where some leading business groups from Madras have applied for permission to the government for land to build super specialist hospitals. In addition in a recent announcement the State is planning to hand over some 'sick' government hospitals to industrialists and NRIs in order to improve the functioning of these insititutions.[7]

Although this brief survey is by no means exhaustive, it is certainly indicative of the emerging scenario in the private sector. While it is well known that both the state-supported medical service and private medical care have been co-existing since independence, in more recent years the latter has been growing and diversifying. The private sector in health care comprises, clinics, small, medium and large nursing homes, hospitals, pathological labs and diagnostic centres. Increasing penetration of high technology equipment is making medical care a profitable venture and has provided a fillip to the expansion of this sector. As a result of this a number of large and regional business groups and doctor entrepreneurs are diversifying into this area. Institutions which use high-tech equipment are no longer confined to the metropolises but are penetrating semi-urban and even rural areas.

There are several reasons for the burgeoning of the private sector. Firstly, although the public sector has expanded considerably since independence, the meagre investments made by the state have been inadequate in meeting rising demand. This 'pent-up' demand is increasingly being met by the private sector. Secondly, the increase in incomes of the middle and upper middle classes, in recent years, has resulted in the demand for durables and luxuries which is reflected in medical care as well. Thirdly, advancement in medical technology has pushed up the cost of medical care making it a profitable business venture. This coupled with liberalisation of import duties on high technology equipment has led to mushrooming of medicare institutions across the country.

Quite clearly, the increase in imports of medical equipment has hiked the cost of medical care. Since most of the high technology equipment is employed for diagnostic purposes, testing has assumed an important role in treatment. As a leading specialist remarked "these days doctors depend excessively on sophisticated testing procedures which have often led to unnecessary testing". Although import of medical equipment is on the rise there has been no effort to either regulate the growth or prescribe minimum standards for the running of these enterprises. Given the profit motive of the private sector, the absence of checks and regulations relegates the welfare of the patient to a secondary position. With the increasing commoditification of medical care and the demand to treat it as an industry, it is mandatory that the government prescribe controls to regulate this sector, the absence of which, will only further distort the existing structure of medical care.

Need for Alternative Medical Education in South Africa

r h philpott

Medical education was introduced in South Africa in 1922 and has since produced many eminent doctors. But today the universities are not producing doctors appropriately trained either for current needs or more disturbingly, for a post-apartheid future. There is an urgent need to radically transform the medical course and curriculum. (Reprinted from Critical Health, *1988)*

DOCTORS first completed their medical education in the University of Cape Town in 1922. The early medical teachers brought their curriculum with them, mainly from the United Kingdom. They produced many first rate doctors and in the decades since, many graduates have attained international acclaim. There have been a number of intra-university curriculum reviews but these have tended to add more and more to an already overfull course. In 1985, the South African Association for Medical Education (SAAME) held a national review of medical education in South Africa, but very few of the recommendations have had any effect on our medical schools. Our universities are neither producing graduates appropriate to the needs of our country at present nor, more disturbingly, for the post-apartheid future. This paper sets out some of the reasons why we urgently need alternative medical education to help solve the serious health care problems in this country, remembering that it will be six years after the new curriculum is established before the first graduates appear.

Maldistribution of Health Services

Doctors tend to practice in the kind of environment where they are taught and so it is understandable that they find their security in city practice, either in this country or overseas. It is true that it will take more than a changed education to entice doctors to practice holistic medicine in the neglected parts of our country, but if we don't change the education we provide, no amount of structural change in the health service will bring about improved health care for the people of South Africa. Doctors need to be trained in the context of where their services are needed most.

Not only does maldistribution operate geographically but also in the emphasis on specialities. For example, many specialist obstetricians with a minimum of twelve years of training spend the bulk of their time doing normal deliveries for extra-ordinarily high fees while primary health care for the poor is seriously neglected.

The major portion of clinical teaching is provided in referral, high-technology teaching hospitals, where the bulk of the country's health budget is spent. This gives students a view of health care that suggests that doctors only deal with rarities and that sophisticated monitoring systems and laboratory investigations are not only indispensable, but immediately available.

The teaching hospital glorifies high-technology curative medicine and surgery and gives limited consideration to preventive and promotive health. Role models have a major influence on the development of a medical student's approach to medical practice, and with the emphasis given to curative medicine and the down-playing of preventive and promotive care, it is little wonder that the same pattern persists in succeeding generations.

There is a need for a medical faculty to develop expertise in the various specialities but this does not promote the most appropriate basis for medical education. It has engendered unhealthy competitiveness for curriculum time, space and status. Each department advances its own course for survival sake and as a result produces a curriculum more suited to specialists in the discipline. Such structures are not suited for the undergraduate education of a 'core' doctors. Instead, there is a need for strong central departments of medical education that co-ordinate cross-discipline, integrated programmes of problem-based learning.

Medical students who graduate from our medical schools have every right to presume that health care is dependent primarily, or even exclusively, on doctors. Their doctor teachers in the hospital are on top of the pile and project other health workers as auxiliaries. Medical students are seldom introduced to other health workers, let alone train with them. Again it is understandable that our graduates have little experience of working in teams and that our country's health service is, in the words of David Werner (author of the book *Where There is No Doctor*) community oppressive rather than community supportive. Doctors are expected to have all the knowledge and wisdom and are not shown how to consult the communities they are meant to serve. They have been trained to be consultants before they learn to consult and to direct before they have learnt to serve.

The tenets of western medical practice are taught as if no other belief and practices have any place in a country with such a multiplicity of cultures. Our very failures should alert us to the need to examine others' successes and to incorporate them into new learning opportunities for our students. A salutary research study conducted in Zimbabwe needs to be heeded by our medical educators. Groups of 100 rural and 100 urban women (many of whom were university graduates) were asked where they would wish to be delivered of their next baby and who they would like as their attendant. The majority in both groups wanted the safety of hospital or maternity clinic but 100 percent of the rural and 90 percent of the urban woman preferred to have a traditional birth attendant (TBA) with them during their labour. Few doctors even

recognise that the overwhelming majority of women on this continent are delivered by TBAs. Instead they write off such patients as 'unbooked' or 'defaulters'. We interpret compliance as meaning taking the host of tablets we prescribe, in spite of the fact that we never explained what they were for. We also forget that our patients have an entirely different world view that informs their understanding of the aetiology and therefore treatment of illness.

Not only do we compartmentalise within our medical faculties, but we isolate the medical schools from all other faculties in the university. How can we expect students to accept other disciplines such as agriculture, economics, sociology and education as being important, if not more important, than medicine in providing health and wholeness of care? We even call one of our schools a Medical University, which is not only a contradiction in terms, but more evidence of our failure to understand what holistic health care is all about. The consequences are a country that can boast the first heart transplant while within walking distance of the particular hospital involved, there are townships with no piped water. The need for a multi-disciplinary approach to teaching extends beyond the compartmentalised medical school to cross the academic barriers in the university. It is only when engineers and agriculturists link with sociologists and physicians in formulating new curricula that the ill-health caused by factors related to each of these disciplines will be addressed. It all seems so obvious, but until we are brave enough to create new educational structures, our students will retreat into their academic enclaves instead of becoming the new pioneers of health care in Southern Africa.

This is not the language of our medical teachers. We are the privileged ones and we are comfortable with our elitist positions and the status quo and bureaucracy that protects our academic safety. Few of us have experienced the oppressive effects of apartheid, the major cause of poverty and ill-health in the midst of this land of great wealth. Without this experience, our teachers are unable to interpret the effects of state systems on community and individual health, and therefore demand that politics and health care be kept in separate compartments.

In spite of the fact that many of our students come from the oppressed communities, their awareness and understanding is not encouraged by the majority of their teachers, and the only oasis in the midst of a year of non-contextualised teaching is the annual Students Conference, at which academic staff are conspicuous by their absence.

The Medical Course

This statement hardly needs elaborating, yet we are all guilty of adding every new discovery to the curriculum, without taking anything out. Each new discovery should remind us that much of the content in today's curriculum will be out of date by the time our students are in practice and our volumes of content will not prepare them for the demands of the new century. We subscribe to 'Health for All by the year 2000' but are not equipping graduates to meet that challenge. Rather than multiplying content we need to provide students with problem-solving skills, for it is that they will be called on to do whether at the community or the individual patient level. Problem-solving will ensure a multi-disciplinary approach to medical education and will equip students to absorb and apply new knowledge as it becomes available. It will also ensure that each subject discipline is dealt with according to its merits, the merit of the solution to common life-saving problems in the first instance, and later, any other problem that may present itself. Students progress when they know how to explore knowledge rather than just memorise it.

We manage to drain every atom of motivation and enthusiasm that students bring with them by our layered curricula, which in the first three years can only suggest to students that life is filled with laboratories, cadavers and specimens in bottles. How much more exciting it is to see a small group of first year students deciding on the anatomy, physiology, pathology etc that they need to explore and learn to enable them to solve a particular clinical problem. By the end of a course of suitably chosen: problem-solving studies they will have not only learnt the principles and content of each subject in the curriculum but they will see how it all fits together in helping them solve the problems. Experience with such curricula has shown that students have to be restrained from over-studying rather than driven through the early years of boredom.

Medical schools are not entirely to blame for suppressing the natural spirit of adventure and exploration. The rot sets in at junior schools. Children, left to themselves, are experiential, self-directed learners until the schools get hold of them. From then on the teacher takes control, and presumes that all children learn at the same pace. Consequently they are regimented into large classrooms, told to keep quiet and listen to the teacher. The only difference at medical school is that the classes are many times larger and the teachers do not even hold an education diploma. My only surprise has been the rapidity with which fourth year university rote learners respond to the liberating experience of changing from an emphasis on whole-class lectures to the fun of problem-solving in small groups. We have shown that it works at that late stage of the curriculum, so why not start that way from the first year of the medical course?

Of all countries in the world today, South Africa in particular needs a liberated educational system. Not only is this the most appropriate way to learn but it equips people to seek after truth and justice in every sphere of their lives.

This outline of the need for alternative medical education in South Africa must point us in the direction of community-based, community-oriented, integrated, problem-solving education as the solution to our needs.

Socio History in Medicine

padma prakash

Medical curricula is in the long run determined by the socio-political needs of the class in charge. Even the content of these disciplines reflects these needs. This article examines the history and curriculum content of one undergraduate discipline in medicine—preventive and social medicine.

THE practice of medicine has undergone tremendous expansion and diversification. Several factors have contributed to the transformation of medical practice, some internal and others external not the least significant of which have been social, political and economic. From time to time medical education has reflected these changes in the practice of medicine. This amalgamation of current practice with training has not taken place in either a smooth progression or as a matter of course. For example while improved methods of diagnosis and treatment have become part of the training of medical graduates with relative rapidity, the growing body of knowledge in epidemiology and in the sociology of health and illness have been all but ignored in the undergraduate medical curriculum. This marginalisation of the sociological perspective has had consequences for the development of medical education and inevitably for the nature of health care.

It is the character of the dominant group/section/class in society which determines the trends and content of medical education. This dominance however, is not because of numerical strength but is a consequence of the historical development of society. Again, what constitutes the requirements of this dominant class is not just derived from the health characteristics of the class/group. For the requirements are rooted in the socio-political needs of the class in charge. In fact not only is the curricula determined largely by these factors, but even the content of these disciplines is tailored to match and sustain the ideological requirements of the dominant class. To illustrate, we examine in the following the history and curriculum content of one undergraduate department, viz preventive and social medicine (PSM). This is a relatively new field, having been introduced as a distinct discipline only in the second quarter of this century. In India separate departments of PSM were established only in the late fifties. What were the factors leading to the introduction of PSM into the undergraduate curriculum? What has been its orientation and what is its current content?

For the purpose of examining in detail the undergraduate curriculum content of PSM we have taken *The Textbook of Preventive and Social Medicine* by J. E. Park and E. Park as a typical illustration. The content preventive and social medicine can only be understood against this background. Specifically, we have looked at Parks' *Textbook of Preventive Medicine* assuming it to illustrate the typical curriculum followed in the department in any undergraduate course.

The textbook is divided into 18 chapters which don't appear to follow any particular sequential logic. A first chapter on what is presumably meant to be a history of medicine is followed with a series genetics and health, sociology and health, environment and health. In a sense of course, the chapterisation is indicative of the entire approach to the subject— that the understanding of the preventive and social aspects of medicine can be so compartmentalised. There appears to be no continuity between the chapters. This criticism will perhaps become clearer when we deal with these chapters in greater detail.

Our main criticism is that the book projects a certain picture of medicine, medical practice, and of the role of the doctor. This creates and reinforces an ideology which is biased against certain sections of society. Moreover it delineates for the medical graduate a methodology for understanding social phenomena which views society as a static, rigidly divided structure. According to this viewpoint the components can each be studied separately, can even be modified, improved, changed. For instance, that health behaviour can be changed without altering the social location of the individual or family concerned. This affords the right grounding for the view that medical solutions can not only be independent of social factors, but in fact they over ride the latter and can even affect social change. While undoubtedly medicine in history has contributed to socio-cultural changes, that it has itself been a product of society is something which is entirely missing in this world view projected by textbooks such as Parks'.

Simultaneously, the book also projects society as a homogeneous entity where everyone has equal access to the conditions which make for health. There is no recognition of the fact that health status, especially in third world conditions is an indicator of the class location (20). This may be best illustrated by the manner in which the authors discuss the problem of malnutrition. Socio-economic factors are listed only as one among the many aspects of the ecology of malnutrition.

The text manages to de-emphasise the fact that malnutrition especially under-nutrition which is the major problem in India, is largely rooted in the lack of purchasing power of certain sections of the population which in turn is again both a cause and consequence of the lack of political power to demand and obtain the wherewithal to lead comfortable lives, live in healthy surroundings and work at non-hazardous occupations. Leave alone the issue of class in society, the book does not even admit sex discrimination in society. Surely a book published in 1985 cannot claim to be

unaware of data on this matter. Any number of studies have shown that women suffer to a greater extent from the problem of malnutrition than do men. Again, in dealing with tuberculosis, the book fails to acknowledge the class-wise distribution of the disease, even though the age and sex trends, time trends and the rural-urban differences are remarked upon.

In general the book tends to medicalise all problems concerning health. Such as for instance malnutrition. Clearly, a social problem it is regarded as a 'medical' problem with social causes and repercussions. Even worse is the way the authors treat mental illness where although social pathological are listed— only third to organic and heredity— the solutions offered stress mainly early diagnosis and rehabilitation just as in any medical problem. The point is except for a small proportion of cases which have organic and hereditary roots, the majority are symptoms of social distress which become manifest in individual aberrations. They can hardly be resolved by 'early diagnosis' of individual cases. The solution lies in the early diagnosis of social distress, which clearly according to Parks is beyond the purview of the doctor.

Not surprisingly, the solutions offered by the authors to any of the range of health problems are either individualist or abstract. That is, what the individual can and must do to avoid falling ill or how the government or more often the health services can offer appropriate measures. That prevention of illness can most effectively be brought about through social action of a group or community. Thus it completely misses out the crucial role the doctor can play in such action by providing the group or community with information etc. In fact right through the book the doctor is regarded as a person being apart and slightly above the rest of society.

Let us now look more closely at some of the chapters in the book. The first, purported to be a history of medicine runs to nine pages. It is pertinent here to note that this is the only department in the undergraduate medical course where the history of medicine figures at all. It was in 1955 recommended the introduction of history as part of the PSM curriculum. In Parks' textbook we have a travelogue through time, enumerating the `advance' of medical knowledge rather than an account of the dynamic interrelationship between medicine and society. The authors' approach is a historical dealing with the developments not in time periods taking into account the social and economic structures of the time, but rather as geographical categories. We have for instance, paragraphs dealing with primitive medicine, Indian medicine, Chinese, Egyptian, Greek and so on. This gives a false notion that the growth of knowledge in medicine has been circumscribed by boundaries of nations and states. In fact, although there were characteristic developments in different countries in numerous periods of history, there has also been a process of dissemination and assimilation between the various centres of civilisation. Modern medicine has its roots in this body of knowledge even though today it may bear little resemblance to it. In consequence the contributions of early medical practitioners and thinkers such as Hippocrates, Galen, are regarded as distinct and separate from that beginning with say, Parcelsus (who "publicity burnt the works of Galen and attacked superstition and dogma in medicine"), Vasalius ("who demonstrated some of Galen's errors") and Ambroise Pare (who "revived surgery and became the father of modern surgery"). While it is true that developments in medicine after the sixteenth century represent a break with the past, the continuity of empirical traditions which is so characteristic of the field does not feature in the narration.

The middle ages ('dismissed by the authors of the book as the dark ages'[1]) saw the development of two distinct traditions of medicine, which were to become competitive in a later period. The inflexibility of the codes of the Catholic church, the widening gap between Church medicine and the people, the famines and plagues, the growing impoverishment provided an impetus for the growth of a more accessible cheaper medical care. Folk medicine which had continued to exist outside the Church, largely in the hands of women, began to encroach upon Church medicine [2] Many historians have seen the witch hunts which were rampant in Europe in the tenth to fourth centuries as the manifestation of the attempts by the Church to usurp the folk knowledge and quell the competing tradition of medicine, one monopolised by the rich feudal lords, the richest of them being the Church, and the other practised by and accessible to the lay poor[3].

Park reviews the beginnings of modern medicine, that is in the 16/17th centuries without ever referring to the tremendous changes that were occuring in the social fabric of the time. So great was the intellectual impact of these discoveries in the field of medicine, that they in turn influenced other sciences and social ideas as well. For instance William Harvey was the first to consciously use scientific methodology in the biomedical sphere. He also used concepts of quantification to arrive at a hypothesis. And used the concept of the human body as a mechanical system with the heart as pump. These are concepts which are integral to clinical medicine today.

Parks' history fails to recognise and trace the ideological trends which are current to this day in medical practice. This would have been possible only if the dynamic interaction between medicine and society is admitted. For example, the predominant social structure of society, cultural practices and prejudices of the seventeenth to the nineteenth centuries, were assimilated in some form or the other into the concepts and content of modern science and medicine which were then evolving.[4] Not surprisingly, medicine's model of a 'normal' human being was a white, adult male. By definition, therefore, women and non-whites were 'abnormal'. These ideas have influenced the development of medicine and set limits on the understanding of particular

pathologies and illness syndromes. Similarly, the mechanistic concept of the body as a machine, as distinct from the mind was to limit the growth of medical knowledge for generations.

At the same time because medicine adapted the dominant ideas of the period, and because it continued to retain its long-standing status in society, it was used to reinforce and substantiate these social myths. Thus for example, because women were by definition all physiological, conditions experienced by them, menstruation, childbirth etc, were regarded as being abnormal and treated as illnesses.[5] Society in turn promoted and perpetuated these ideas by taking resort to medical opinion. This fact that throughout history medicine and its practitioners have largely been oriented towards supporting and sustaining dominant ideas, often to the detriment of the socially oppressed classes is an important aspect of history unfortunately given a miss by Parks' textbook. In short, the first chapter of the book is a disoriented, disjointed account of history which really ought not to have been there at all. If at all the history of medicine is to be taught to medical students, it ought to receive a more coherent, sociological treatment than the one presented here.

Sociology of Medicine

We now look at two chapters which give us an idea of the sociological concepts presented by the authors. The book deals with sociology more as a set of terms to be defined rather than as a body of knowledge with a long history. Like other disciplines sociology too, a plethora of theories, orientations and schools of thought have richly contributed to its development. Park however, is either unaware of these developments or regards but one school of thought as being important. This approach will undoubtedly leave the medical student with a slightly jaundiced view of the discipline. More importantly, the book does not deal with methods of sociological analysis which are so necessary for the delivery of health care.

The chapter on 'sociology and health' deals with the following "concepts in sociology": society, social structure, social institutions, role, socialism, socialisation, social control mechanisms, customs, culture, acculturation, standard of living, social problems, social pathology, social surveys, case study, field study, communications and social defence in that order. Need we say anything at all about this? One is hard put to understand the logic and the purpose of such a list of 'concepts'. Admittedly these are terms which need to be explained, but they are not concepts. Even the terms cannot be understood by mechanical definitions. Each has to be understood historically, its meaning often having changed with time and the context. Moreover, even the choice of 'concepts' so defined appears biased. Such important concepts as social movements, or social change and what they constitute, do not figure here.

It is also significant that in defining social structure the inherently conflicting relationship between classes (or strata, as Parks would call it) is not recognised. The fact is that some groups are more empowered than others and that these power relationships cannot be altered without shaking the very roots of society.

Society has been defined in a number of ways by different sociologists. In the evolutionary model all societies pass through definite stages of development. For some social thinkers like Durkhiem the most important dimension of society is the degree of specialisation within it which is progressively complex as societies pass through the different stages. In the structural functionalist model it is the interrelationship of social institutions rather than the individual or group which is to be emphasised.[6] Talcott Parsons modelled his conception of society on the theory of homeostasis and saw society as constantly attempting to balance its equilibrium by automatic adjustments when upset by internal or external forces.

Parks' textbook appears to have no use at all for this variety of ways in which thinkers have understood society. This is even more true of the other 'concepts'. Certainly it is utterly ridiculous to try to define socialism in 14 printed lines.

What little there is of sociology in the textbook is almost entirely Parsonian. Talcott Parsons developed the concept of the sick role in his writings have greatly influenced medical sociology. According to this understanding there are four essential aspects of the sick role— the sick person is exempted from his normal social role responsibilities; the sick person cannot help being ill; the sick person is expected to get well as soon as possible and finally he is expected to seek help in getting well. Parsons therefore emphasised the need to control sickness. Consequently, social control is clearly a function of the medical establishment.[7]

Not surprisingly of course, the textbook deals with social institutions such as the family as being "the most powerful example of social cohesion" which have existed in all societies. "The family is a primary unit in all societies." It is well-accepted today that the family, defined as the authors do viz, "a group of biologically related individuals living together and eating from a common kitchen." was not in fact a primary unit in all societies. Quite clearly, the Parks notion of the family is patriarchal: "The family is a bridge between generations and between fathers and sons." And again, "The family provides social care by ... giving status in a society to its members ie use of family names..." At one point the book talks of how the "freedom of wives" has enlarged and of how "the young wife in India...brings to a marriage not only a dowry but a professional or semi-professional education and she seeks a professional career." There are several points to be made here. First, the changing family structure is a consequence of a number of factors, economic, cultural and social and second, the status women in the family and their role, as well as the functions of the family are not universally the same. Even within one

country they vary with class, region and culture. And third, while it is true that dowry is a widespread phenomena, to refer to it as an inevitable and accepted feature of society is not quite correct.

The discussions on the family in the textbook are particularly important because 'social and community medicine' confers a significant role on the family in disseminating its message. Thus for instance, the family's traditional role or rather the role of the women in the family, in child bearing, health and nursing care, are the via media through which ideas can be propogated from generation to generation, thus ensuring the perpetuation of the social structure as it exists currently.

Another chapter which is a hotch potch is the one on community health. After attempting to define health in a crudely mechanistic way and outlining the relationship between health and development, the chapter moves on to a definition of disease— the interaction of the agent, host and environment etc, and then on to a description of health situation and the health services. While such an explanation for understanding disease may be useful, it can also tend too mechanical. Evidently the result of the interaction of the three is often much greater than the sum of the three. Moreover, it is not possible to change the nature of one without inevitably altering the other two. Altering, say the disease agent may not be possible without simultaneously changing the characteristics of the other two.

Nowhere in all this do we find a definition of community. This is a concept which has created much discussion among sociologists. If by community is meant a group which shares common socio-political features, then a village comprises several communities and it is absurd to talk of a village community as if it is homogeneous. Community medicine is a meaningless concept if 'community' is not defined.

To sum up, in this book preventive and social medicine has the following characteristics : (1) Ill health is viewed as a consequence of the interaction of man and nature where the changes in the latter are beyond our control. The essence of medicine is to help 'man' make the necessary changes so as to balance the changes in nature. (2) The activities of the individual are the major reasons for ill health — viz, use of unclean water sources causes typhoid, cholera etc, smoking causes cancer, inadequate iron intake causes anaemia, babies die because mothers don't breastfeed, workers die because their work environment is unhealthy and so on. The object of PSM is to teach medical students to help individuals, alter their lifestyles without damaging social institutions and norms. (3) The social and political forces in society do not significantly affect the development of medicine or health policy, and the history of thought (including medicine) may be viewed as a set of isolable, distinct phases with little spillover. (4) society is generally uniformly cohesive. Although there are groups and stratas, they do not have inherently conflicting interests and may live together in peace and health. (5) The human body is a mechanical system and organs are component parts which may be repaired or replaced. In the same fashion all health problems may be reduced to the malfunctioning of a particular part of the subsystem. Biological man rather than the social human being is the ideal. (6) Health is defined and understood in terms of an individual's productive capacity and not the quality of life. By this definition, a worker is termed healthy as long as he can achieve a certain level of productivity. The individual must therefore be helped to maintain this level of productivity irrespective of whether he feels healthy. In short, PSM justifies existing socio-economic and political formation by arguing that the aberrations seen in the system are not intrinsic to it but are a result of individual behaviour and may be smoothed over by persuading individuals in 'communities' to accept their fault and remedy the situation. An approach to medicine which has the potential to show up the inherent contradictions in patriarchal class society which in reality determine the health status of a society, has effectively been defused.

The exercise undertaken here is only illustrative, but it does indicate that the orientation of preventive and social medicine reinforces the socio-political framework which papers over major contradictions in society. It helps to justify existing socio-economic and political formation by arguing that the aberrations seen in the system, in this case in the health status of the population, are not intrinsic to it but are a result of individual behaviour or minor faults which may be smoothed over or repaired. If the practice of medicine is to become more relevant, it is here in the department of PSM that the restructuring must start.

[This article is an abridged version of a paper appearing in an anthology on Medical Education published by the Medico Friend Circle. (In the Press)]

An Uneasy Relationship

sucheta amin

Law and Medical Ethics by J K Mason and Smith McCall R A, Butterworth 1987 (Second Edition), pp 344, $ 12.95. It should not be correct to say that every moral obligation involves a legal duty, but every legal duty is founded on a moral obligation — Lord Chief Justice Coleridge in R.V. Instan (1893) 1QBat 453.

THIS second edition of the book takes account of recent legislation and much of the text, including chapters on reproductive techniques, consent and euthanasia has been rewritten. There is also a new chapter on the treatment of the elderly and the Mental Health Act 1983 is also considered. With the introduction it covers five major topics viz: reproductive medicine, medical practice, death, research and experimentation and psychiatry and the law. The list of cases and table of statistics along with appendices is also given.

The first section on evolution of medical ethics briefly follows the progress through the earlier periods to the organisation of modern medicine. This section also introduces medical ethics and legal intervention in medicine. The crucial question raised is that of determining the extent to which medical decisions should be the object of legal scrutiny and control. Two extreme views exist, one that holds that the medical profession should be left to regulate itself and that it alone should decide what is acceptable conduct. The contrary view expressed, denies doctors the right to regulate their relationship with their patients ie reserving for the medical profession the right to decide on issues of life and death is an improper derogation from an area of legitimate public concern and an encrochment by clinicians into what is, properly, social policy. Broadly speaking these conflicting views are those of two groups representing the medical profession holding the first viewpoint and the patients who are treated by these medical professionals holding the latter view-point. The legal system then is faced with the classic problem of doing justice to both parties. The fear of the medical profession must be taken into account while the legitimate claims of the patient cannot be ignored.

The second section dealing with reproductive medical covers (a) A Reform of Sex Law? (b) Modern Reproductive Technology (c) Control of Fertility (d) Abortion (e) Prenatal and Wrongful Life (f) Neonaticide and selective treatment of the newborn.

Under the topic a reform of sex law, this book deals briefly with application of law with regard to sexual intercourse, rape, homosexuality, incest, transexualism etc. "Full expression of ones sexuality is now advocated in some countries by responsible educational authorities. Medical knowledge and expertise are moving to serve the changing needs of people. It is doubtful on the other hand if our present sex laws to accurately reflect current public mores". The topic of rape ie sexual intercourse without consent briefly but concisely brings out various issues related to the subject. They almost take a stand when they state "our feeling is that 'rape' is essentially an act of violence in which sexuality plays only a secondary part. It also brings out the outdated existing laws in the United Kingdom where rape, to be raped requires intercourse per vulvam.' There is a brief mention of approach to rape in different countries. There is a humane though condescending attitude taken by the authors towards homosexuals and transexuals. As for incest when it is sexual abuse on children by a trusted elder then there can be no place for law that protect such abusers.

Modern reproductive technology has been extensively covered in this book. Being a very sensitive issue needing intense consideration of both legal and ethical issues. The authors seem to be taking a very practical view when they state 'methods are now available for by-passing the natural process. Almost inevitably, these sometimes conflict with laws which were mainly fashioned before such techniques were considered.

If we look at the different reproductive techniques offered at their exorbitant rates, it is a highly commercialised process. So let us not be under the impression that it is concern for childless couples that such techniques have emerged. Why are absurd techniques like amniocentesis in vogue today? Is it to help facilitate female foeticide under the garb of helping correct genetic defects? Why should fascist ideas of eliminating imperfect foetus be encouraged? In almost all cases the woman who has to go through all the painful procedure has someone else making decisions for her. The major being the 'stigma' attached to being infertile. Surrogate motherhood is a mockery of motherhood the way it stands today. The word someone had coined 'technological adultery' would more apt here. There is so much about abortion and laws relating to it. Why is not the woman left to decide whether she wants to abort or not? It is her body, her right to decide. If the socio-economic pressures are the main reason a woman goes in for abortion, why aren't laws passed to deal with exploitation that is going on. Instead of whether the heart was beating at the time the foetus was aborted?

The chapter on medical practice looks into issues relating to medical confidentiality, consent to treatment, treatment of the aged. The above mentioned issues are points of con-

flict between law and medical ethics. The authors have presented the issues illustrated with actual cases. Laws relating to medical ethics emerged as a safeguard against exploitation by of the medical profession. Being a reflection of the capitalist social structure, compensations (torts) will be demanded for medical malpractices. It is inevitable because the patient has his/her right since they are paying for the services. Counsel regarding treatment of the aged is a clear indication of the economic climate and is unlikely to be followed in the foreseeable future.

The topic on 'Death' deals with diagnosis of death, donations of organs and transplantation, euthanasia Biomedical human experimentation, Research on children and foetal experimentation. Issues over which medical profession could exert their power. Euthanasia whether active or passive, voluntary or involuntary is reflective of a person's right to life. The question I would like to raise is whose life is it? Donation of organs and transplantation is once again based on financial gains except a few philanthrophists who would donate organs from the goodness of heart. Though research is necessary for its benefits to humanity, the way it is used for commercial purposes leaves one aghast. Then we need to look within, to question our motives.

The extent to which psychiatry can operate as a political or social weapon constitutes its importance in the current debate. A broad sympathetic view may prevent the unjust punishment of those who are truly not responsible for their action but it may also prove to be socially damaging if criminals are left free under the garb of insanity. The inescapable task then becomes one of charting a course between Scyulla and Charybdis. To achieve this the criminal law should adhere to a broad definition of insanity (such as in Scottish or French formulae : refer page 307) which allows maximum leeway for a court to take into account expert evidence while at the same time avoiding necessarily being bound to an acceptance of psychiatric notions of reponsibility.

This book is a good reference volume with its pragmatic approach to different issues illustrated by actual cases. It covers topics relating to law and medical ethics in United Kingdom. These issues can hardly be considered applicable in Indian context where law itself if negligent, let alone medical ethics.

SUBSCRIPTION RENEWALS

Is this your last subscribed issue? A prompt renewal from you will ensure that your copy is mailed directly from the Press. Many of our issues have sold out fast! So book your copies by renewing your subscription now!

Our new subscription rates:

For individuals—Rs. 30/- (four issues)

(Contd from Pg. No.4)

peatedly stressed that scientists and technologists ought to accorded higher status and emoluments. The Shrivastava ommittee, MCI and other highly placed authorities unuivocally recommended non-practising terms for the edical teachers. The administration has not taken their commendations in the right spirit. There has developed a xus of mutual interest between the political-bureaucratic thority and the teaching community. Politicians of all ades and bureaucrats enjoy the free services of teacherecialists who also make the costly medicare facilities of e state hospitals available to the former out-of-turn. It is deed difficult to find a political leader or a high governent official who is not personally obliged to a medical acher. In fact, one of the topmost physicians of Calcutta enly maintained unauthorised private practice throughout e entire length of his service career occupying nonactising posts, which included the topmost posts in the st-graduate medical college and the health service in West engal: this enterprising doctor professionally served the ief ministers and ministers during both Congress and Left ont regimes. Unless this pernicious system of private actice is removed, other measures will be infructuous. ll discriminations in the matter of pay, promotion and reement benefits should be resolved. More and more unirsity control should be introduced replacing government ntrol. There should be a declared policy of transfer in nsferable services. Lastly and most importantly, there ght to be a system of assessment of performance accomnied by incentives and disincentives. This is perhaps the ost controversial area and difficult to operate. Because, edibility of assessment depends upon the credibility and mpetence of assessors. Still, a structural framework for ements and procedure for assessment could be devised and given a trial. If this is done, then the present system of aminations based on subjective assessment could be rown away and be replaced by periodic objective assessent of students at every crucial level of curriculum and aining.

The task of updating of knowledge should not be left to dividual initiative. Updating includes revision and is pendent on research. It may be emphasised that the aching community is the most effective force in research d the poor state of medical research in India is actually a flection of the teaching community.

The Bhore Committee observed in 1946.

"No special facilities are available for the training teachers in the different subjects of the medical curriulum. . . Broadly speaking medical research receives little no attention in the medical colleges of India. The thorities responsible for staffing and financing the medi- colleges are usually ignorant of the importance of search in relation to the achievement of a correct attitude mind in the students. . . " The role of teachers in shapg the make-up students is crucial and nowhere is it more pronounced than in the field of medical education. The attitude towards both science and society is involved. The student is influenced not only by the teachings and preachings of the teacher but is influenced most by the teacher's practice. The teacher's admonition against indiscriminate use of antibiotics or random use of steroids cuts little ice with the student when the latter discovers the very teacher's indiscriminate and random prescriptions in private practice. The student thus learns the difference between theory and practice and this influence is intensive and sustained, shaping the professional career and attitude of the student. The teacher's conduct, in its turn, is detemined by his/her position in the society and the profession. Social and economic compulsions dictate terms. In the conflict between pursuit of science and commercial gain, the latter generally prevails. Medical education cannot wait for the development of the intrinsic goodwill of the teachers. Unless measures are taken to ensure job satisfaction, medical colleges will always remain short of dedicated teachers. Unless the standard of teachers is improved, teaching can never improve and consequently medical care cannot improve, however, grandiose or rational might be the curriculum or methodology of teaching. Unfortunately this profound role of teachers in medical education is yet to be recognised in India.

Appeal to Subscribers/Readers

We regret that the last few issues of the *Radical Journal of Health* have been delayed. This has been because of printing and other difficulties, none of which fortunately are insurmountable. We hope to bring the publication up-to-date in the next couple of months. Please bear with us!

The RJH is for you and is sustained mainly by the support of regular readers like you. So far the journal is being subsidised by donations from concerned individuals. We would not like to pass on the burden of the extra cost to our readers by increasing the subscription rates. The Socialist Health Review Trust, the publisher of RJH has started a campaign for creating a corpus fund which can continue to asborb the extra cost as far as possible.

We appeal to you and your friends to generously contribute to this fund. *All donations may be made payable to the Socialist Health Review Trust and are exempted from Income Tax under Section 80G of the Income Tax Act.*

Why don't you write for us?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in ealth issues. The chief aim of the journal is to provide a forum of exchange of ideas and for generating a debate on ractical and theoretical issues in health for a **radical or Marxist** perspective. We believe that only through such nteraction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in arlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of he date of publication which means that the issue on Medical Technology is already being worked on. A full length rticle should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated, authors' names in the case of joint authorship will be printed in alphabetical order. You will ppreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing f reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes e have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this ue.

All articles should be sent in duplicate. They should be neatly typed in double spacing on one side of the sheet. his is necessary because we do not have office facilities here and the press requires all materials to be typed. But if is impossible for you to get the material typed, do not let it stop you from sending us your contributions in a neat **andwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words nd sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact rough your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Radical Journal of Health for one year (four issues). I am sending Rs._____ as subscription and/or donation by Demand Draft/ Cheque. (DD and cheque in favour of Radical Journal of Health and for cheque add Rs.5, if outside Bombay).

On Eliminating Quackery

The laws against quackery were intended to protect physicians in their special interests, to secure their curative privileges; the patients were put under the guardianship of the government, of the patronising police state. The modern state which is to establish the equal rights of free citizenship must therefore, automatically be against the maintenance of the law of quackery. . .

. . . We must (now) ask how the state. . . can and shall prevent quackery. For it cannot be denied that it lies in the public interest to restrain as far as possible the treatment of patients by ignorant persons.

The main tool of democracy is education. If we raise the educational level of physicians as well as that of laymen, quackery will correspondingly become less frequent. The more perfect the educational institutions of the state, the more scientific and practical medical education, the stricter and the more careful the medical examinations, the more realiable will be the physicians, "accredited by the government" and officially recommended to the lamyen and the greater will be the confidence they will meet and acquire. . . . But just as important, or perhaps even more so, is the education of the layman. As long as our schools devote their main efforts to the transmission of certain types only of knowledge and of doctrines consolidating belief in authority, in the best of cases, producing a sterile scholarship; as long as education, from primary school, to university is not throughout based on perception by our senses, as long as it does not aim to maintain and increase by critical faculty and by the power of independent thought, a sound, genuine and unadultered human understanding side by side with a large fund of positive knowledge in the natural sciences and in natural history, the basis will be lacking which would enable the layman to form his own judgement on his physicians and pseudophysicians. Not only the uneducated but also the educated laymen, the common as well as the outstanding people, will remain servilely subordinate to medical authority and a resounding title such as a privy court, or sanitary counsellor will constitute a most lucrative shingle for the medical quack. . . . Let a few generations pass — and that which now appears as just a logical postulate, as a pious wish will turn out to be an actual necessity, a cultural achievement.

— Rudolf Virchow
